Bipartite Matching

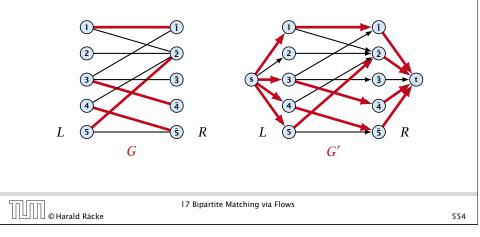

- A matching *M* is perfect if it is of cardinality |M| = |V|/2.
- ► For a bipartite graph $G = (L \uplus R, E)$ this means |M| = |L| = |R| = n.

Proof

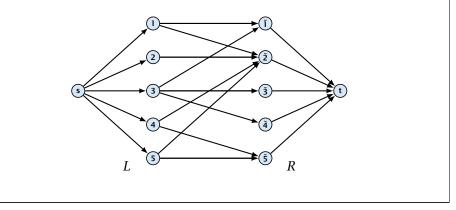

Max cardinality matching in $G \leq$ value of maxflow in G'

- Given a maximum matching *M* of cardinality *k*.
- Consider flow *f* that sends one unit along each of *k* paths.
- f is a flow and has cardinality k.

17 Bipartite Matching via Flows

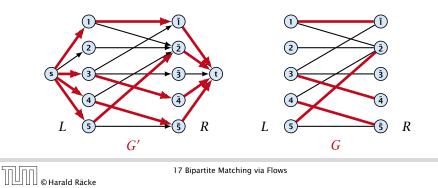

- ▶ Input: undirected, bipartite graph $G = (L \uplus R \uplus \{s, t\}, E')$.
- ► Direct all edges from *L* to *R*.
- Add source *s* and connect it to all nodes on the left.
- Add *t* and connect all nodes on the right to *t*.
- All edges have unit capacity.

Proof

Max cardinality matching in $G \ge$ value of maxflow in G'

- Let f be a maxflow in G' of value k
- Integrality theorem $\Rightarrow k$ integral; we can assume f is 0/1.
- Consider M= set of edges from L to R with f(e) = 1.
- Each node in L and R participates in at most one edge in M.
- |M| = k, as the flow must use at least k middle edges.

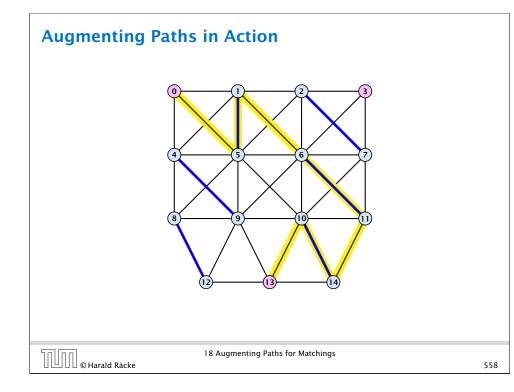

17 Bipartite Matching via Flows

Which flow algorithm to use?

- Generic augmenting path: $\mathcal{O}(m \operatorname{val}(f^*)) = \mathcal{O}(mn)$.
- Capacity scaling: $\mathcal{O}(m^2 \log C) = \mathcal{O}(m^2)$.

18 Augmenting Paths for Matchings

Definitions.

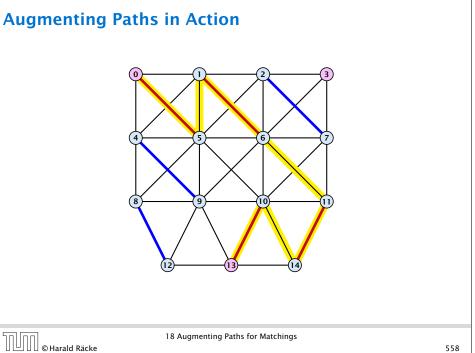

- Given a matching M in a graph G, a vertex that is not incident to any edge of *M* is called a free vertex w.r. t. *M*.
- For a matching M a path P in G is called an alternating path if edges in M alternate with edges not in M.
- An alternating path is called an augmenting path for matching M if it ends at distinct free vertices.

Theorem 1

A matching M is a maximum matching if and only if there is no augmenting path w.r.t. M.
