Parallel Algorithms

Due date: November 24th, 2014 before class!

Problem 1 (10 Points)

Show how to reduce the merging of two sorted sequences of lengths n and m to the ANSV problem corresponding to an array of length n + m.

Problem 2 (10 Points)

Recall: A binary sequence is *bitonic* if it is a concatenation of two subsequences such that one is monotonically increasing and the other is monotonically decreasing, or vice versa. A sequence $X = (x_0, \ldots, x_{n-1})$ is *bitonic* if, for some j < n, we have

 $x_{j \mod n} \le x_{(j+1) \mod n} \le \dots \le x_{\ell \mod n} \quad \text{and}$ $x_{(\ell+1) \mod n} \ge x_{(\ell+2) \mod n} \ge \dots \ge x_{(j+n-1) \mod n}$

for some ℓ . That is, the circle $x_0 \to x_1 \to \cdots \to x_{n-1} \to x_0$ can be partitioned into two monotonic parts.

Show the zero-one principle for bitonic sequences: An n-input comparator network is a bitonic merging network if and only if it merges correctly all binary bitonic sequences of length n.

Problem 3 (10 Points)

Show that a bitonic merging network can be constructed as follows:

- Given a bitonic sequence, merge $(x_1, x_3, x_5, ...)$ and $(x_2, x_4, x_6, ...)$ in bitonic mergers whose lines are interleaved,
- compare and interchange the outputs in pairs $(x_1, x_2), (x_3, x_4), (x_5, x_6), \ldots$
