## Matchings

## Matching

- Input: undirected graph $G=(V, E)$.
- $M \subseteq E$ is a matching if each node appears in at most one edge in $M$.
- Maximum Matching: find a matching of maximum cardinality

## Bipartite Matching

- Input: undirected, bipartite graph $G=(L \uplus R, E)$.
- $M \subseteq E$ is a matching if each node appears in at most one edge in $M$.
- Maximum Matching: find a matching of maximum cardinality

## Bipartite Matching

- Input: undirected, bipartite graph $G=(L \uplus R, E)$.
- $M \subseteq E$ is a matching if each node appears in at most one edge in $M$.
- Maximum Matching: find a matching of maximum cardinality

## Bipartite Matching

- A matching $M$ is perfect if it is of cardinality $|M|=|V| / 2$.
- For a bipartite graph $G=(L \uplus R, E)$ this means $|M|=|L|=|R|=n$.

## 19 Bipartite Matching via Flows

- Input: undirected, bipartite graph $G=\left(L \uplus R \uplus\{s, t\}, E^{\prime}\right)$.
- Direct all edges from $L$ to $R$.
- Add source $s$ and connect it to all nodes on the left.
- Add $t$ and connect all nodes on the right to $t$.
- All edges have unit capacity.

## Proof

Max cardinality matching in $G \leq$ value of maxflow in $G^{\prime}$

- Given a maximum matching $M$ of cardinality $k$.
- Consider flow $f$ that sends one unit along each of $k$ paths.
- $f$ is a flow and has cardinality $k$.

## Proof

Max cardinality matching in $G \geq$ value of maxflow in $G^{\prime}$

- Let $f$ be a maxflow in $G^{\prime}$ of value $k$
- Integrality theorem $\Rightarrow k$ integral; we can assume $f$ is $0 / 1$.
- Consider $M=$ set of edges from $L$ to $R$ with $f(e)=1$.
- Each node in $L$ and $R$ participates in at most one edge in $M$.
- $|M|=k$, as the flow must use at least $k$ middle edges.

## 19 Bipartite Matching via Flows

## Which flow algorithm to use?

- Generic augmenting path: $\mathcal{O}\left(m \operatorname{val}\left(f^{*}\right)\right)=\mathcal{O}(m n)$.
- Capacity scaling: $\mathcal{O}\left(m^{2} \log C\right)=\mathcal{O}\left(m^{2}\right)$.

EADS

## 20 Augmenting Paths for Matchings

## Definitions.

- Given a matching $M$ in a graph $G$, a vertex that is not incident to any edge of $M$ is called a free vertex w.r. .t. $M$.
- For a matching $M$ a path $P$ in $G$ is called an alternating path if edges in $M$ alternate with edges not in $M$.
- An alternating path is called an augmenting path for matching $M$ if it ends at distinct free vertices.

Theorem 95
A matching $M$ is a maximum matching if and only if there is no augmenting path w.r.t. M.

## Augmenting Paths in Action

## 20 Augmenting Paths for Matchings

## Proof.

$\Rightarrow$ If $M$ is maximum there is no augmenting path $P$, because we could switch matching and non-matching edges along $P$. This gives matching $M^{\prime}=M \oplus P$ with larger cardinality.
$\Leftarrow$ Suppose there is a matching $M^{\prime}$ with larger cardinality. Consider the graph $H$ with edge-set $M^{\prime} \oplus M$ (i.e., only edges that are in either $M$ or $M^{\prime}$ but not in both).

Each vertex can be incident to at most two edges (one from $M$ and one from $M^{\prime}$ ). Hence, the connected components are alternating cycles or alternating path.

As $\left|M^{\prime}\right|>|M|$ there is one connected component that is a path $P$ for which both endpoints are incident to edges from $M^{\prime} . P$ is an alternating path.

## 20 Augmenting Paths for Matchings

## Algorithmic idea:

As long as you find an augmenting path augment your matching using this path. When you arrive at a matching for which no augmenting path exists you have a maximum matching.

Theorem 96
Let $G$ be a graph, $M$ a matching in $G$, and let $u$ be a free vertex w.r.t. M. Further let $P$ denote an augmenting path w.r.t. $M$ and let $M^{\prime}=M \oplus P$ denote the matching resulting from augmenting $M$ with $P$. If there was no augmenting path starting at $u$ in $M$ then there is no augmenting path starting at $u$ in $M^{\prime}$.

[^0]
## 20 Augmenting Paths for Matchings

## Proof

- Assume there is an augmenting path $P^{\prime}$ w.r.t. $M^{\prime}$ starting at $u$.
- If $P^{\prime}$ and $P$ are node-disjoint, $P^{\prime}$ is also augmenting path w.r.t. $M$ (k).
- Let $u^{\prime}$ be the first node on $P^{\prime}$ that is in $P$, and let $e$ be the matching edge from $M^{\prime}$ incident to $u^{\prime}$.
- $u^{\prime}$ splits $P$ into two parts one of which does not contain $e$. Call this part $P_{1}$. Denote the sub-path of $P^{\prime}$ from $u$ to $u^{\prime}$ with $P_{1}^{\prime}$.
- $P_{1} \circ P_{1}^{\prime}$ is augmenting path in $M$ (z).

## How to find an augmenting path?

Construct an alternating tree.

## 21 Weighted Bipartite Matching

## Weighted Bipartite Matching/Assignment

- Input: undirected, bipartite graph $G=L \cup R, E$.
- an edge $e=(\ell, r)$ has weight $w_{e} \geq 0$
- find a matching of maximum weight, where the weight of a matching is the sum of the weights of its edges

Simplifying Assumptions (wlog [why?]):

- assume that $|L|=|R|=n$
- assume that there is an edge between every pair of nodes $(\ell, r) \in V \times V$

## Weighted Bipartite Matching

Theorem 97 (Halls Theorem)
A bipartite graph $G=(L \cup R, E)$ has a perfect matching if and only if for all sets $S \subseteq L,|\Gamma(S)| \geq|S|$, where $\Gamma(S)$ denotes the set of nodes in $R$ that have a neighbour in $S$.

## Halls Theorem

## Proof:

$\Leftarrow$ Of course, the condition is necessary as otherwise not all nodes in $S$ could be matched to different neigbhours.
$\Rightarrow$ For the other direction we need to argue that the minimum cut in the graph $G^{\prime}$ is at least $|L|$.

- Let $S$ denote a minimum cut and let $L_{S} \stackrel{\text { def }}{=} L \cap S$ and $R_{S} \stackrel{\text { det }}{=} R \cap S$ denote the portion of $S$ inside $L$ and $R$, respectively.
- Clearly, all neighbours of nodes in $L_{S}$ have to be in $S$, as otherwise we would cut an edge of infinite capacity.
- This gives $R_{S} \geq\left|\Gamma\left(L_{S}\right)\right|$.
- The size of the cut is $|L|-\left|L_{S}\right|+\left|R_{S}\right|$.
- Using the fact that $\left|\Gamma\left(L_{S}\right)\right| \geq L_{S}$ gives that this is at least $|L|$.

## Algorithm Outline

## Idea:

We introduce a node weighting $\vec{x}$. Let for a node $v \in V, x_{v} \geq 0$ denote the weight of node $v$.

- Suppose that the node weights dominate the edge-weights in the following sense:

$$
x_{u}+x_{v} \geq w_{e} \text { for every edge } e=(u, v)
$$

- Let $H(\vec{x})$ denote the subgraph of $G$ that only contains edges that are tight w.r.t. the node weighting $\vec{x}$, i.e. edges $e=(u, v)$ for which $w_{e}=(u, v)$.
- Try to compute a perfect matching in the subgraph $H(\vec{x})$. If you are successful you found an optimal matching.

## Algorithm Outline

## Reason:

- The weight of your matching $M^{*}$ is

$$
\sum_{(u, v) \in M^{*}} w_{(u, v)}=\sum_{(u, v) \in M^{*}}\left(x_{u}+x_{v}\right)=\sum_{v} x_{v}
$$

- Any other matching $M$ has

$$
\sum_{(u, v) \in M} w_{(u, v)} \leq \sum_{(u, v) \in M}\left(x_{u}+x_{v}\right) \leq \sum_{v} x_{v}
$$

## Algorithm Outline

## What if you don't find a perfect matching?

Then, Halls theorem guarantees you that there is a set $S \subseteq L$, with
$|\Gamma(S)|<|S|$, where $\Gamma$ denotes the neighbourhood w.r.t. the subgraph $H(\vec{x})$.

Idea: reweight such that:

- the total weight assigned to nodes decreases
- the weight function still dominates the edge-weights

If we can do this we have an algorithm that terminates with an optimal solution (we analyze the running time later).

## Changing Node Weights

Increase node-weights in $\Gamma(S)$ by $+\delta$, and decrease the node-weights in $S$ by $-\delta$.

- Total node-weight decreases.
- Only edges from $S$ to $R-\Gamma(S)$ decrease in their weight.
- Since, none of these edges is tight (otw. the edge would be contained in $H(\vec{x})$, and hence would go between $S$ and $\Gamma(S)$ ) we can do this decrement for small enough $\delta>0$ until a new edge gets tight.

## Weighted Bipartite Matching

Edges not drawn have weight 0 .

$$
\delta=1 \delta=1
$$

## Analysis

How many iterations do we need?

- One reweighting step increases the number of edges out of $S$ by at least one.
- Assume that we have a maximum matching that saturates the set $\Gamma(S)$, in the sense that every node in $\Gamma(S)$ is matched to a node in $S$ (we will show that we can always find $S$ and a matching such that this holds).
- This matching is still contained in the new graph, because all its edges either go between $\Gamma(S)$ and $S$ or between $L-S$ and $R-\Gamma(S)$.
- Hence, reweighting does not decrease the size of a maximum matching in the tight sub-graph.

## Analysis

- We will show that after at most $n$ reweighting steps the size of the maximum matching can be increased by finding an augmenting path.
- This gives a polynomial running time.

EADS

## Analysis

## How do we find $S$ ?

- Start on the left and compute an alternating tree, starting at any free node $u$.
- If this construction stops, there is no perfect matching in the tight subgraph (because for a perfect matching we need to find an augmenting path starting at $u$ ).
- The set of even vertices is on the left and the set of odd vertices is on the right and contains all neighbours of even nodes.
- All odd vertices are matched to even vertices. Furthermore, the even vertices additionally contain the free vertex $u$. Hence, $\left|V_{\text {odd }}\right|=\left|\Gamma\left(V_{\text {even }}\right)\right|<\left|V_{\text {even }}\right|$, and all odd vertices are saturated in the current matching.

## Analysis

- The current matching does not have any edges from $V_{\text {odd }}$ to outside of $L \backslash V_{\text {even }}$ (edges that may possibly deleted by changing weights).
- After changing weights, there is at least one more edge connecting $V_{\text {even }}$ to a node outside of $V_{\text {odd }}$. After at most $n$ reweights we can do an augmentation.
- A reweighting can be trivially performed in time $\mathcal{O}\left(n^{2}\right)$ (keeping track of the tight edges).
- An augmentation takes at most $\mathcal{O}(n)$ time.
- In total we otain a running time of $\mathcal{O}\left(n^{4}\right)$.
- A more careful implementation of the algorithm obtains a running time of $\mathcal{O}\left(n^{3}\right)$.

## A Fast Matching Algorithm

```
Algorithm 54 Bimatch-Hopcroft-Karp \((G)\)
    1: \(M \leftarrow \emptyset\)
    2: repeat
    3: \(\quad\) let \(\mathcal{P}=\left\{P_{1}, \ldots, P_{k}\right\}\) be maximal set of
    4: vertex-disjoint, shortest augmenting path w.r.t. \(M\).
    5: \(\quad M \leftarrow M \oplus\left(P_{1} \cup \cdots \cup P_{k}\right)\)
6: until \(\mathcal{P}=\emptyset\)
7: return \(M\)
```

We call one iteration of the repeat-loop a phase of the algorithm.

## Analysis

## Lemma 98

Given a matching $M$ and a maximal matching $M^{*}$ there exist $\left|M^{*}\right|-|M|$ vertex-disjoint augmenting path w.r.t. $M$.

## Proof:

- Similar to the proof that a matching is optimal iff it does not contain an augmenting paths.
- Consider the graph $G=\left(V, M \oplus M^{*}\right)$, and mark edges in this graph blue if they are in $M$ and red if they are in $M^{*}$.
- The connected components of $G$ are cycles and paths.
- The graph contains $k \stackrel{\text { def }}{=}\left|M^{*}\right|-|M|$ more red edges than blue edges.
- Hence, there are at least $k$ components that form a path starting and ending with a blue edge. These are augmenting paths w.r.t. $M$.

## Analysis

- Let $P_{1}, \ldots, P_{k}$ be a maximal collection of vertex-disjoint, shortest augmenting paths w.r.t. $M$ (let $\left.\ell=\left|P_{i}\right|\right)$.
- $M^{\prime} \stackrel{\text { def }}{=} M \oplus\left(P_{1} \cup \cdots \cup P_{k}\right)=M \oplus P_{1} \oplus \cdots \oplus P_{k}$.
- Let $P$ be an augmenting path in $M^{\prime}$.

Lemma 99
The set $A \stackrel{\text { def }}{=} M \oplus\left(M^{\prime} \oplus P\right)=\left(P_{1} \cup \cdots \cup P_{k}\right) \oplus P$ contains at least $(k+1) \ell$ edges.

## Analysis

## Proof.

- The set describes exactly the symmetric difference between matchings $M$ and $M^{\prime} \oplus P$.
- Hence, the set contains at least $k+1$ vertex-disjoint augmenting paths w.r.t. $M$ as $\left|M^{\prime}\right|=|M|+k+1$.
- Each of these paths is of length at least $\ell$.

## Analysis

## Lemma 100

$P$ is of length at least $\ell+1$. This shows that the length of $a$ shortest augmenting path increases between two phases of the Hopcroft-Karp algorithm.

## Proof.

- If $P$ does not intersect any of the $P_{1}, \ldots, P_{k}$, this follows from the maximality of the set $\left\{P_{1}, \ldots, P_{k}\right\}$.
- Otherwise, at least one edge from $P$ coincides with an edge from paths $\left\{P_{1}, \ldots, P_{k}\right\}$.
- This edge is not contained in $A$.
- Hence, $|A| \leq k \ell+|P|-1$.
- The lower bound on $|A|$ gives $(k+1) \ell \leq|A| \leq k \ell+|P|-1$, and hence $|P| \geq \ell+1$.

## Analysis

If the shortest augmenting path w.r.t. a matching $M$ has $\ell$ edges then the cardinality of the maximum matching is of size at most $|M+| \frac{|V|}{\ell+1}$.

## Proof.

The symmetric difference between $M$ and $M^{*}$ contains $\left|M^{*}\right|-|M|$ vertex-disjoint augmenting paths. Each of these paths contains at least $\ell+1$ vertices. Hence, there can be at most $\frac{|V|}{\ell+1}$ of them.

## Analysis

Lemma 101
The Hopcroft-Karp algorithm requires at most $2 \sqrt{|V|}$ phases.

Proof.

- After iteration $\lfloor\sqrt{|V|}\rfloor$ the length of a shortest augmenting path must be at least $\lfloor\sqrt{|V|}\rfloor+1 \geq \sqrt{|V|}$.
- Hence, there can be at most $|V| /(\sqrt{|V|}+1) \leq \sqrt{|V|}$ additional augmentations.

## Analysis

## Lemma 102

One phase of the Hopcroft-Karp algorithm can be implemented in time $\mathcal{O}(m)$.

## How to find an augmenting path?

Construct an alternating tree.

## even nodes odd nodes

Case 4: $y$ is already contained in $T$ as an even vertex can't ignore $y$

The cycle $w \leftrightarrow y-x \leftrightarrow w$ is called a blossom.
$w$ is called the base of the blossom (even node!!!).
The path $u-w$ path is called the stem of the blossom.

## Flowers and Blossoms

Definition 103
A flower in a graph $G=(V, E)$ w.r.t. a matching $M$ and a (free) root node $r$, is a subgraph with two components:

- A stem is an even length alternating path that starts at the root node $r$ and terminates at some node $w$. We permit the possibility that $r=w$ (empty stem).
- A blossom is an odd length alternating cycle that starts and terminates at the terminal node $w$ of a stem and has no other node in common with the stem. $w$ is called the base of the blossom.

## Flowers and Blossoms

## Flowers and Blossoms

## Properties:

1. A stem spans $2 \ell+1$ nodes and contains $\ell$ matched edges for some integer $\ell \geq 0$.
2. A blossom spans $2 k+1$ nodes and contains $k$ matched edges for some integer $k \geq 1$. The matched edges match all nodes of the blossom except the base.
3. The base of a blossom is an even node (if the stem is part of an alternating tree starting at $r$ ).

## Flowers and Blossoms

## Properties:

4. Every node $x$ in the blossom (except its base) is reachable from the root (or from the base of the blossom) through two distinct alternating paths; one with even and one with odd length.
5. The even alternating path to $x$ terminates with a matched edge and the odd path with an unmatched edge.

## Flowers and Blossoms

When during the alternating tree construction we discover a blossom $B$ we replace the graph $G$ by $G^{\prime}=G / B$, which is obtained from $G$ by contracting the blossom $B$.

- Delete all vertices in $B$ (and its incident edges) from $G$.
- Add a new (pseudo-)vertex $b$. The new vertex $b$ is connected to all vertices in $V \backslash B$ that had at least one edge to a vertex from $B$.

## Shrinking Blossoms

- Edges of $T$ that connect a node $u$ not in $B$ to a node in $B$ become tree edges in $T^{\prime}$ connecting $u$ to b.
- Matching edges (there is at most one) that connect a node $u$ not in $B$ to a node in $B$ become matching edges in $M^{\prime}$.
- Nodes that are connected in $G$ to at least one node in $B$ become connected to $b$ in $G^{\prime}$.

```
Algorithm 55 search(r, found)
    1: set }\overline{A}(i)\leftarrowA(i)\mathrm{ for all nodes }
    2: found}\leftarrow\mathrm{ false
    3: unlabel all nodes;
    4: give an even label to }r\mathrm{ and initialize list }\leftarrow{r
    5: while list # \emptyset do
    6: delete a node i from list
    7: examine(i,found)
    8: if found = true then
    9: return
```

```
Algorithm 56 examine( \(i\), found)
    1: for all \(j \in \bar{A}(i)\) do
    2: \(\quad\) if \(j\) is even then contract \((i, j)\) and return
    3: \(\quad\) if \(j\) is unmatched then
    4: \(\quad q \leftarrow j\);
    5: \(\quad \operatorname{pred}(q) \leftarrow i\);
    6: found \(\leftarrow\) true;
    7: return
    8: \(\quad\) if \(j\) is matched and unlabeled then
    9: \(\quad \operatorname{pred}(j) \leftarrow i\);
10: \(\quad \operatorname{pred}(\operatorname{mate}(j)) \leftarrow j\);
```

```
Algorithm 57 contract(i,j)
    1: trace pred-indices of i and j to identify a blossom B
    2: create new node b and set }\overline{A}(b)\leftarrow\mp@subsup{\cup}{x\inB}{}\overline{A}(k
    3: label b even and add to list
    4: update }\overline{A}(j)\leftarrow\overline{A}(j)\cup{b}\mathrm{ for each }j\in\overline{A}(b
    5: form a circular doubly linked list of nodes in B
    6: delete nodes in B from the graph
```

## Example: Blossom Algorithm

Assume that we have contracted a blossom $B$ w.r.t. a matching $M$ whose base is $w$. We created graph $G^{\prime}=G / B$ with pseudonode $b$. Let $M^{\prime}$ be the matching in the contracted graph.

## Lemma 104

If $G^{\prime}$ contains an augmenting path $p^{\prime}$ starting at $r$ (or the pseudo-node containing $r$ ) w.r.t. to the matching $M^{\prime}$ then $G$ contains an augmenting path starting at $r$ w.r.t. matching $M$.

## Proof.

If $p^{\prime}$ does not contain $b$ it is also an augmenting path in $G$.

## Case 1: nonempty stem

- Next suppose that the stem is nonempty.

- After the expansion $\ell$ must be incident to some node in the blossom. Let this node be $k$.
- If $k \neq w$ there is an alternating path $P_{2}$ from $w$ to $k$ that ends in a matching edge.
- $P_{1} \circ(i, w) \circ P_{2} \circ(k, \ell) \circ P_{3}$ is an alternating path.
- If $k=w$ then $P_{1} \circ(i, w) \circ(w, \ell) \circ P_{3}$ is an alternating path.

## Proof.

## Case 2: empty stem

- If the stem is empty then after expanding the blossom, $w=r$.

- The path $r \circ P_{2} \circ(k, \ell) \circ P_{3}$ is an alternating path.

## Lemma 105

If $G$ contains an augmenting path $P$ from $r$ to $q$ w.r.t. matching $M$ then $G^{\prime}$ contains an augmenting path from $r$ (or the pseudo-node containing $r$ ) to $q$ w.r.t. $M^{\prime}$.

EADS

## Proof.

- If $P$ does not contain a node from $B$ there is nothing to prove.
- We can assume that $r$ and $q$ are the only free nodes in $G$.

## Case 1: empty stem

Let $i$ be the last node on the path $P$ that is part of the blossom.
$P$ is of the form $P_{1} \circ(i, j) \circ P_{2}$, for some node $j$ and $(i, j)$ is unmatched.
$(b, j) \circ P_{2}$ is an augmenting path in the contracted network.

## Case 2: non-empty stem

Let $P_{3}$ be alternating path from $r$ to $w$. Define $M_{+}=M \oplus P_{3}$. In $M_{+}, r$ is matched and $w$ is unmatched.
$G$ must contain an augmenting path w.r.t. matching $M_{+}$, since $M$ and $M_{+}$have same cardinality.

This path must go between $w$ and $q$ as these are the only unmatched vertices w.r.t. $M_{+}$.

For $M_{+}^{\prime}$ the blossom has an empty stem. Case 1 applies.
$G^{\prime}$ has an augmenting path w.r.t. $M_{+}^{\prime}$. It must also have an augmenting path w.r.t. $M^{\prime}$, as both matchings have the same cardinality.

This path must go between $r$ and $q$.

## Example: Blossom Algorithm

[^0]:    The above theorem allows for an easier implementation of an augmenting path algorithm. Once we checked for augmenting paths starting I from $u$ we don't have to check for such paths in future rounds.
