# **Dynamic Set Operations**

- S. search(k): Returns pointer to object x from S with key[x] = k or null.
- S. insert(x): Inserts object x into set S. key[x] must not currently exist in the data-structure.
- S. delete(x): Given pointer to object x from S, delete x from the set.
- **S. minimum()**: Return pointer to object with smallest key-value in S.
- S. maximum(): Return pointer to object with largest key-value in S.
- ► *S*. successor(*x*): Return pointer to the next larger element in *S* or null if *x* is maximum.
- S. predecessor(x): Return pointer to the next smaller element in *S* or null if *x* is minimum.

EADS 🛛 🖓 © Ernst Mayr, Harald Räcke

# **Abstract Data Type**

An abstract data type (ADT) is defined by an interface of operations or methods that can be performed and that have a defined behavior.

The data types in this lecture all operate on objects that are represented by a [key, value] pair.

- The key comes from a totally ordered set, and we assume that there is an efficient comparison function.
- > The value can be anything; it usually carries satellite information important for the application that uses the ADT.

EADS © Ernst Mayr, Harald Räcke

# **Examples of ADTs**

#### Stack:

- S.push(x): Insert an element.
- S.pop(): Return the element from S that was inserted most recently; delete it from S.
- S.empty(): Tell if S contains any object.

#### Queue:

- ► *S*.enqueue(*x*): Insert an element.
- S.dequeue(): Return the element that is longest in the structure; delete it from S.
- **S.empty()**: Tell if S contains any object.

#### **Priority-Queue:**

- ► *S*.insert(*x*): Insert an element.
- S.delete-min(): Return the element with lowest key-value; delete it from S.

# 7 Dictionary

#### Dictionary:

- S.insert(x): Insert an element x.
- ► *S*.delete(*x*): Delete the element pointed to by *x*.
- S.search(k): Return a pointer to an element *e* with key[*e*] = k in S if it exists; otherwise return null.

EADS © Ernst Mayr, Harald Räcke 7 Dictionary

#### 125

# 7.1 Binary Search Trees

An (internal) binary search tree stores the elements in a binary tree. Each tree-node corresponds to an element. All elements in the left sub-tree of a node v have a smaller key-value than key[v] and elements in the right sub-tree have a larger-key value. We assume that all key-values are different.

(External Search Trees store objects only at leaf-vertices)

#### Examples:

# 7.1 Binary Search Trees

We consider the following operations on binary search trees. Note that this is a super-set of the dictionary-operations.

- T. insert(x)
- ► T. delete(x)
- ► *T*. search(*k*)
- ► T. successor(x)
- T. predecessor(x)
- T. minimum()
- T. maximum()

Element does not have any children

Simply go to the parent and set the corresponding pointer to null.

 Splice the element out of the tree by connecting its parent to its successor.

# **Binary Search Trees: Delete**

5

elect $y$ to splice out
s child of $y$ (or null)
parent[x] is correct
fix pointer to <i>x</i>
J

# **Balanced Binary Search Trees**

All operations on a binary search tree can be performed in time  $\mathcal{O}(h)$ , where h denotes the height of the tree.

However the height of the tree may become as large as  $\Theta(n)$ .

#### **Balanced Binary Search Trees**

With each insert- and delete-operation perform local adjustments to guarantee a height of  $O(\log n)$ .

AVL-trees, Red-black trees, Scapegoat trees, 2-3 trees, B-trees, AA trees, Treaps

similar: SPLAY trees.

# 7.2 Red Black Trees

#### **Definition 1**

A red black tree is a balanced binary search tree in which each internal node has two children. Each internal node has a color, such that

- 1. The root is black.
- 2. All leaf nodes are black.
- **3.** For each node, all paths to descendant leaves contain the same number of black nodes.
- 4. If a node is red then both its children are black.

The null-pointers in a binary search tree are replaced by pointers to special null-vertices, that do not carry any object-data

# 7.2 Red Black Trees

#### Lemma 2

A red-black tree with n internal nodes has height at most  $O(\log n)$ .

#### **Definition 3**

The black height bh(v) of a node v in a red black tree is the number of black nodes on a path from v to a leaf vertex (not counting v).

We first show:

#### Lemma 4

A sub-tree of black height bh(v) in a red black tree contains at least  $2^{bh(v)} - 1$  internal vertices.

7.2 Red Black Trees	
Proof of Lemma 4.	
Induction on the height of $v$ .	
<b>base case</b> (height( $v$ ) = 0)	
<ul> <li>If height(v) (maximum distance btw. v and a node in the sub-tree rooted at v) is 0 then v is a leaf.</li> <li>The black height of v is 0.</li> </ul>	
<ul> <li>The sub-tree rooted at v contains 0 = 2<sup>bh(v)</sup> - 1 inner vertices.</li> </ul>	
EADS 7.2 Red Black Trees	139

7.2 Red Black Trees

# 7.2 Red Black Trees

#### **Proof (cont.)**

#### induction step

- Supose v is a node with height(v) > 0.
- $\triangleright$  v has two children with strictly smaller height.
- These children ( $c_1$ ,  $c_2$ ) either have  $bh(c_i) = bh(v)$  or  $bh(c_i) = bh(v) - 1.$
- By induction hypothesis both sub-trees contain at least  $2^{bh(v)-1} - 1$  internal vertices.
- Then  $T_{\nu}$  contains at least  $2(2^{bh(\nu)-1}-1) + 1 \ge 2^{bh(\nu)} 1$ vertices.

# 7.2 Red Black Trees

# 7.2 Red Black Trees

#### **Definition 1**

A red black tree is a balanced binary search tree in which each internal node has two children. Each internal node has a color, such that

- 1. The root is black.
- 2. All leaf nodes are black.
- 3. For each node, all paths to descendant leaves contain the same number of black nodes.
- 4. If a node is red then both its children are black.

The null-pointers in a binary search tree are replaced by pointers to special null-vertices, that do not carry any object-data.

#### EADS 🛛 🖓 © Ernst Mayr, Harald Räcke

# 7.2 Red Black Trees

#### Proof of Lemma 2.

Let h denote the height of the red-black tree, and let P denote a path from the root to the furthest leaf.

At least half of the node on *P* must be black, since a red node must be followed by a black node.

Hence, the black height of the root is at least h/2.

The tree contains at least  $2^{h/2} - 1$  internal vertices. Hence,  $2^{h/2} - 1 < n$ .

Hence,  $h \leq 2\log(n+1) = \mathcal{O}(\log n)$ .

EADS © Ernst Mayr, Harald Räcke

7.2 Red Black Trees

# Rotations

The properties will be maintained through rotations:

# Red Black Trees: Insert Invariant of the fix-up algorithm: *z* is a red node the black-height property is fulfilled at every node the only violation of red-black properties occurs at *z* and parent[*z*] either both of them are red (most important case) or the parent does not exist (violation since root must be black) If *z* has a parent but no grand-parent we could simply color the parent/root black; however this case never happens.

Algorithm 10 InsertFix(z)		
1: while $parent[z] \neq null and col[parent[z]] = red do$		
2:	<b>if</b> parent[ $z$ ] = left[gp[ $z$ ]] <b>then</b> $z$ in left	subtree of grandparent
3:	$uncle \leftarrow right[grandparent[z]]$	
4:	<pre>if col[uncle] = red then</pre>	Case 1: uncle red
5:	$\operatorname{col}[p[z]] \leftarrow \operatorname{black}; \operatorname{col}[u] \leftarrow \operatorname{black};$	ack;
6:	$\operatorname{col}[\operatorname{gp}[z]] \leftarrow \operatorname{red}; z \leftarrow \operatorname{grandpa}$	rent[z];
7:	else	Case 2: uncle black
8:	<pre>if z = right[parent[z]] then</pre>	2a: <i>z</i> right child
9:	$z \leftarrow p[z]; LeftRotate(z);$	
10:	$col[p[z]] \leftarrow black; col[gp[z]]$	← red;2b: <i>z</i> left child
11:	RightRotate $(gp[z]);$	
12:	else same as then-clause but right and	l left exchanged
13: col	$(root[T]) \leftarrow black;$

EADS © Ernst Mayr, Harald Räcke

# Red Black Trees: Insert

#### **Running time:**

- Only Case 1 may repeat; but only h/2 many steps, where h is the height of the tree.
- Case  $2a \rightarrow Case 2b \rightarrow red-black$  tree
- Case  $2b \rightarrow$  red-black tree

Performing Case 1 at most  $O(\log n)$  times and every other case at most once, we get a red-black tree. Hence  $O(\log n)$ re-colorings and at most 2 rotations.

# **Red Black Trees: Delete**

First do a standard delete.

If the spliced out node x was red everything is fine.

If it was black there may be the following problems.

- Parent and child of *x* were red; two adjacent red vertices.
- If you delete the root, the root may now be red.
- Every path from an ancestor of x to a descendant leaf of x changes the number of black nodes. Black height property might be violated.

EADS 7.2 Red Black Trees	152

#### Delete:

- deleting black node messes up black-height property
- if *z* is red, we can simply color it black and everything is fine
- the problem is if z is black (e.g. a dummy-leaf); we call a fix-up procedure to fix the problem.

Red Black Trees: Delete	
Invariant of the fix-up algorithm	
the node z is black	
<ul> <li>if we "assign" a fake black unit to the edge from z to its parent then the black-height property is fulfilled</li> </ul>	
<b>Goal:</b> make rotations in such a way that you at some point can remove the fake black unit from the edge.	

# Case 2: Sibling is black with two black children

#### **Running time:**

- only Case 2 can repeat; but only h many steps, where h is the height of the tree
- Case 1  $\rightarrow$  Case 2 (special)  $\rightarrow$  red black tree Case 1  $\rightarrow$  Case 3  $\rightarrow$  Case 4  $\rightarrow$  red black tree Case 1  $\rightarrow$  Case 4  $\rightarrow$  red black tree
- Case  $3 \rightarrow$  Case  $4 \rightarrow$  red black tree
- $\blacktriangleright$  Case 4  $\rightarrow$  red black tree

Performing Case 2 at most  $O(\log n)$  times and every other step at most once, we get a red black tree. Hence,  $O(\log n)$ re-colorings and at most 3 rotations.

# 7.3 AVL-Trees

#### **Definition 5**

AVL-trees are binary search trees that fulfill the following balance condition. For every node v

 $|\text{height}(\text{left sub-tree}(v)) - \text{height}(\text{right sub-tree}(v))| \le 1$ .

#### Lemma 6

An AVL-tree of height h contains at least  $F_{h+2} - 1$  and at most  $2^{h} - 1$  internal nodes, where  $F_{n}$  is the *n*-th Fibonacci number  $(F_0 = 0, F_1 = 1)$ , and the height is the maximal number of edges from the root to an (empty) dummy leaf.

# **Red-Black Trees** Bibliography [CLRS90] Thomas H. Cormen, Charles E. Leiserson, Ron L. Rivest, Clifford Stein: Introduction to Algorithms (3rd ed.), MIT Press and McGraw-Hill, 2009 Red black trees are covered in detail in Chapter 13 of [CLRS90]. EADS © Ernst Mayr, Harald Räcke 7.2 Red Black Trees 161

# **AVL trees**

#### Proof.

nn EADS

The upper bound is clear, as a binary tree of height *h* can only contain

$$\sum_{j=0}^{h-1} 2^j = 2^h - 1$$

internal nodes.

# **AVL trees**

#### **Proof (cont.)**

Induction (base cases):

- 1. an AVL-tree of height h = 1 contains at least one internal node,  $1 \ge F_3 1 = 2 1 = 1$ .
- 2. an AVL tree of height h = 2 contains at least two internal nodes,  $2 \ge F_4 1 = 3 1 = 2$

 $\mathcal{Q}$ 

EADS © Ernst Mayr, Harald Räcke

163

165

# 7.3 AVL-Trees

An AVL-tree of height h contains at least  $F_{h+2} - 1$  internal nodes. Since

7.3 AVL-Trees

 $n+1 \ge F_{h+2} = \Omega\left(\left(rac{1+\sqrt{5}}{2}
ight)^h
ight)$  ,

we get

EADS

U]]] © Ernst Mayr, Harald Räcke

$$n \ge \Omega\left(\left(\frac{1+\sqrt{5}}{2}\right)^{h}\right)$$

7.3 AVL-Trees

and, hence,  $h = O(\log n)$ .

#### Induction step:

An AVL-tree of height  $h \ge 2$  of minimal size has a root with sub-trees of height h - 1 and h - 2, respectively. Both, sub-trees have minmal node number.

#### Let

 $g_h := 1 + \text{minimal size of AVL-tree of height } h$ .

Then

$= F_3$
$= F_4$
hence
$= F_{h+2}$

# 7.3 AVL-Trees

We need to maintain the balance condition through rotations.

For this we store in every internal tree-node v the balance of the node. Let v denote a tree node with left child  $c_{\ell}$  and right child  $c_r$ .

 $balance[v] := height(T_{c_{\ell}}) - height(T_{c_{r}})$ ,

where  $T_{c_{\ell}}$  and  $T_{c_{r}}$ , are the sub-trees rooted at  $c_{\ell}$  and  $c_{r}$ , respectively.

EADS © Ernst Mayr, Harald Räcke

# **Rotations**

The properties will be maintained through rotations:

# **AVL-trees: Insert**

Note that before the insertion w is right above the leaf level, i.e., x replaces a child of w that was a dummy leaf.

- Insert like in a binary search tree.
- Let *w* denote the parent of the newly inserted node *x*.
- One of the following cases holds:

- If  $bal[w] \neq 0$ ,  $T_w$  has changed height; the balance-constraint may be violated at ancestors of w.
- Call AVL-fix-up-insert(parent[w]) to restore the balance-condition.

# **AVL-trees: Insert**

EADS

©Ernst Mayr, Harald Räcke

#### Invariant at the beginning of AVL-fix-up-insert(v):

- 1. The balance constraints hold at all descendants of v.
- **2.** A node has been inserted into  $T_c$ , where c is either the right or left child of v.
- **3.**  $T_c$  has increased its height by one (otw. we would already have aborted the fix-up procedure).
- **4.** The balance at node *c* fulfills balance  $[c] \in \{-1, 1\}$ . This holds because if the balance of c is 0, then  $T_c$  did not change its height, and the whole procedure would have been aborted in the previous step.

169

Note that these constraints hold for the first call AVL-fix-up-insert(parent[w]).

# **AVL-trees: Insert**

Algorithm 11 AVL-fix-up-insert(v)

- 1: **if** balance[v]  $\in \{-2, 2\}$  **then** DoRotationInsert(v);
- 2: if balance  $[v] \in \{0\}$  return;
- 3: AVL-fix-up-insert(parent[v]);

We will show that the above procedure is correct, and that it will do at most one rotation.

EADS © Ernst Mayr, Harald Räcke

7.3 AVL-Trees

171

# **AVL-trees: Insert**

It is clear that the invariant for the fix-up routine holds as long as no rotations have been done.

We have to show that after doing one rotation all balance constraints are fulfilled.

We show that after doing a rotation at v:

- $\triangleright$  v fulfills balance condition.
- $\blacktriangleright$  All children of v still fulfill the balance condition.
- $\blacktriangleright$  The height of  $T_v$  is the same as before the insert-operation took place.

We only look at the case where the insert happened into the right sub-tree of v. The other case is symmetric.

nn EADS

EAUS © Ernst Mayr, Harald Räcke

# **AVL-trees: Insert**

# **AVL-trees: Insert** We have the following situation: The right sub-tree of v has increased its height which results in a balance of -2 at v. Before the insertion the height of $T_v$ was h + 1.

7.3 AVL-Trees

# **AVL-trees: Delete**

- Delete like in a binary search tree.
- Let v denote the parent of the node that has been spliced out.
- The balance-constraint may be violated at v, or at ancestors of v, as a sub-tree of a child of v has reduced its height.
- Initially, the node c—the new root in the sub-tree that has changed—is either a dummy leaf or a node with two dummy leafs as children.

In both cases bal[c] = 0.

• Call AVL-fix-up-delete(v) to restore the balance-condition.

50 (nn	EADS	
	© Ernst Mayr, Harald Räd	cke

7.3 AVL-Trees

# **AVL-trees: Delete**

#### Invariant at the beginning AVL-fix-up-delete(v):

- 1. The balance constraints holds at all descendants of v.
- **2.** A node has been deleted from  $T_c$ , where c is either the right or left child of v.
- **3.**  $T_c$  has decreased its height by one.
- **4.** The balance at the node c fulfills balance[c] = 0. This holds because if the balance of c is in  $\{-1, 1\}$ , then  $T_c$  did not change its height, and the whole procedure would have been aborted in the previous step.

# **AVL-trees: Delete**

Algorithm 13 AVL-fix-up-delete(v)

- 1: **if** balance  $[v] \in \{-2, 2\}$  **then** DoRotationDelete(v);
- 2: if balance  $[v] \in \{-1, 1\}$  return;
- 3: AVL-fix-up-delete(parent[v]);

We will show that the above procedure is correct. However, for the case of a delete there may be a logarithmic number of rotations.

Crost Mayr, Harald Bäcko	

7.3 AVL-Trees

179

# **AVL-trees: Delete**

It is clear that the invariant for the fix-up routine hold as long as no rotations have been done.

We show that after doing a rotation at v:

- $\triangleright$  v fulfills the balance condition.
- All children of v still fulfill the balance condition.
- If now balance  $[v] \in \{-1, 1\}$  we can stop as the height of  $T_v$ is the same as before the deletion.

We only look at the case where the deleted node was in the right sub-tree of v. The other case is symmetric.

# **AVL-trees: Delete**

181

nn EADS

© Ernst Mayr, Harald Räcke

If the middle subtree has height h the whole tree has height h + 2 as before the deletion. The iteration stops as the balance at the root is non-zero.

If the middle subtree has height h - 1 the whole tree has decreased its height from h + 2 to h + 1. We do continue the fix-up procedure as the balance at the root is zero.

# 7.4 Augmenting Data Structures

#### Suppose you want to develop a data structure with:

- Insert(x): insert element x.
- **Search**(*k*): search for element with key *k*.
- **Delete**(*x*): delete element referenced by pointer *x*.
- Find-by-rank(ℓ): return the ℓ-th element; return "error" if the data-structure contains less than ℓ elements.

# Augment an existing data-structure instead of developing a new one.

# 7.4 Augmenting Data Structures

#### How to augment a data-structure

- 1. choose an underlying data-structure
- 2. determine additional information to be stored in the underlying structure
- 3. verify/show how the additional information can be maintained for the basic modifying operations on the underlying structure.

	• (	Of course, the above steps heavily depend
4. develop the new operations	i c	on each other. For example it makes no

	· · · · · · · · · · · · · · · · · · ·
erations	on each other. For example it makes no
	sense to choose additional information to
	be stored (Step 2), and later realize that
	either the information cannot be maintained
	efficiently (Step 3) or is not sufficient to
	support the new operations (Step 4).
	• However, the above outline is a good way to
	describe/document a new data-structure.

# Rotations

The only operation during the fix-up procedure that alters the tree and requires an update of the size-field:

The nodes x and z are the only nodes changing their size-fields.

The new size-fields can be computed locally from the size-fields of the children.

EADS 7.4 Augmenting Data Structures © Ernst Mayr, Harald Räcke 191

# 7.5 (*a*, *b*)-trees

#### **Definition 7**

For  $b \ge 2a - 1$  an (a, b)-tree is a search tree with the following properties

- 1. all leaves have the same distance to the root
- 2. every internal non-root vertex v has at least a and at most b children
- 3. the root has degree at least 2 if the tree is non-empty
- 4. the internal vertices do not contain data, but only keys (external search tree)
- 5. there is a special dummy leaf node with key-value  $\infty$

# 7.5 (*a*, *b*)-trees

Each internal node v with d(v) children stores d - 1 keys  $k_1, \ldots, k_d - 1$ . The *i*-th subtree of v fulfills

 $k_{i-1} < ext{ key in } i ext{-th sub-tree } \leq k_i$  ,

```
where we use k_0 = -\infty and k_d = \infty.
```

EADS © Ernst Mayr, Harald Räcke 7.5 (a, b)-trees

193

# 7.5 (*a*, *b*)-trees

#### Variants

- The dummy leaf element may not exist; it only makes implementation more convenient.
- Variants in which b = 2a are commonly referred to as *B*-trees.
- A *B*-tree usually refers to the variant in which keys and data are stored at internal nodes.
- A B<sup>+</sup> tree stores the data only at leaf nodes as in our definition. Sometimes the leaf nodes are also connected in a linear list data structure to speed up the computation of successors and predecessors.
- A B\* tree requires that a node is at least 2/3-full as opposed to 1/2-full (the requirement of a B-tree).

# 7.5 (*a*, *b*)-trees

#### Example 8

#### Lemma 9

Let T be an (a, b)-tree for n > 0 elements (i.e., n + 1 leaf nodes) and height h (number of edges from root to a leaf vertex). Then

- 1.  $2a^{h-1} \le n+1 \le b^h$
- 2.  $\log_b(n+1) \le h \le 1 + \log_a(\frac{n+1}{2})$

#### Proof.

- If n > 0 the root has degree at least 2 and all other nodes have degree at least a. This gives that the number of leaf nodes is at least 2a<sup>h-1</sup>.
- Analogously, the degree of any node is at most b and, hence, the number of leaf nodes at most b<sup>h</sup>.

# Search

#### Search(19)

The search is straightforward. It is only important that you need to go all the way to the leaf.

Time:  $\mathcal{O}(b \cdot h) = \mathcal{O}(b \cdot \log n)$ , if the individual nodes are organized as linear lists.

EADS	7.5 ( <i>a</i> , <i>b</i> )-tree
🛛 🕒 🛛 🖉 © Ernst Mayr, Harald Räcke	

# Insert

#### Rebalance(v):

EADS

- Let  $k_i$ , i = 1, ..., b denote the keys stored in v.
- Let  $j := \lfloor \frac{b+1}{2} \rfloor$  be the middle element.
- Create two nodes  $v_1$ , and  $v_2$ .  $v_1$  gets all keys  $k_1, \ldots, k_{i-1}$ and  $v_2$  gets keys  $k_{i+1}, \ldots, k_h$ .
- Both nodes get at least  $\lfloor \frac{b-1}{2} \rfloor$  keys, and have therefore degree at least  $\lfloor \frac{b-1}{2} \rfloor + 1 \ge a$  since  $b \ge 2a - 1$ .
- They get at most  $\lceil \frac{b-1}{2} \rceil$  keys, and have therefore degree at most  $\lceil \frac{b-1}{2} \rceil + 1 \le b$  (since  $b \ge 2$ ).
- The key  $k_i$  is promoted to the parent of v. The current pointer to v is altered to point to  $v_1$ , and a new pointer (to the right of  $k_i$ ) in the parent is added to point to  $v_2$ .
- Then, re-balance the parent.

#### Insert

#### Insert(7)

#### Delete

Delete element *x* (pointer to leaf vertex):

- Let v denote the parent of x. If key[x] is contained in v, remove the key from v, and delete the leaf vertex.
- Otherwise delete the key of the predecessor of x from v; delete the leaf vertex; and replace the occurrence of key[x] in internal nodes by the predecessor key. (Note that it appears in exactly one internal vertex).
- ► If now the number of keys in v is below a 1 perform Rebalance'(v).

# Delete

Rebalance'(v):

- If there is a neighbour of v that has at least a keys take over the largest (if right neighbor) or smallest (if left neighbour) and the corresponding sub-tree.
- If not: merge v with one of its neighbours.
- The merged node contains at most (a − 2) + (a − 1) + 1 keys, and has therefore at most 2a − 1 ≤ b successors.
- Then rebalance the parent.
- During this process the root may become empty. In this case the root is deleted and the height of the tree decreases.

# 7.6 Skip Lists

205

207

Choose ratios between list-lengths evenly, i.e.,  $\frac{|L_{i-1}|}{|L_i|} = r$ , and, hence,  $L_k \approx r^{-k}n$ .

Worst case running time is:  $\mathcal{O}(r^{-k}n + kr)$ . Choose  $r = n^{\frac{1}{k+1}}$ . Then

$$r^{-k}n + kr = \left(n^{\frac{1}{k+1}}\right)^{-k}n + kn^{\frac{1}{k+1}}$$
$$= n^{1-\frac{k}{k+1}} + kn^{\frac{1}{k+1}}$$
$$= (k+1)n^{\frac{1}{k+1}} .$$

Choosing  $k = \Theta(\log n)$  gives a logarithmic running time.

EADS © Ernst Mayr, Harald Räcke 7.6 Skip Lists

# 7.6 Skip Lists

#### How to do insert and delete?

If we want that in L<sub>i</sub> we always skip over roughly the same number of elements in L<sub>i-1</sub> an insert or delete may require a lot of re-organisation.

#### **Use randomization instead!**

EADS © Ernst Mayr, Harald Räcke

7.6 Skip Lists

# 7.6 Skip Lists

#### Insert:

- A search operation gives you the insert position for element x in every list.
- Flip a coin until it shows head, and record the number t ∈ {1,2,...} of trials needed.
- Insert x into lists  $L_0, \ldots, L_{t-1}$ .

#### Delete:

- > You get all predecessors via backward pointers.
- Delete *x* in all lists it actually appears in.

# The time for both operations is dominated by the search time.

# High Probability

#### **Definition 10 (High Probability)**

We say a **randomized** algorithm has running time  $O(\log n)$  with high probability if for any constant  $\alpha$  the running time is at most  $O(\log n)$  with probability at least  $1 - \frac{1}{n^{\alpha}}$ .

Here the  $\mathcal{O}$ -notation hides a constant that may depend on  $\alpha$ .

EADS © Ernst Mayr, Harald Räcke

# **High Probability**

Suppose there are a polynomially many events  $E_1, E_2, ..., E_\ell$ ,  $\ell = n^c$  each holding with high probability (e.g.  $E_i$  may be the event that the *i*-th search in a skip list takes time at most  $O(\log n)$ ).

Then the probability that all  $E_i$  hold is at least

 $\Pr[E_1 \wedge \dots \wedge E_{\ell}] = 1 - \Pr[\bar{E}_1 \vee \dots \vee \bar{E}_{\ell}]$  $\geq 1 - n^c \cdot n^{-\alpha}$  $= 1 - n^{c-\alpha} .$ 

This means  $\Pr[E_1 \land \cdots \land E_\ell]$  holds with high probability.

7.6 Skip Lists	213
	7.6 Skip Lists

# 7.6 Skip Lists

#### Lemma 11

A search (and, hence, also insert and delete) in a skip list with n elements takes time O(logn) with high probability (w. h. p.).

$$\left(\frac{n}{k}\right)^{k} \leq {\binom{n}{k}} \leq \left(\frac{en}{k}\right)^{k}$$

$$\binom{n}{k} = \frac{n!}{k! \cdot (n-k)!} = \frac{n \cdot \ldots \cdot (n-k+1)}{k \cdot \ldots \cdot 1} \geq \left(\frac{n}{k}\right)^{k}$$

$$\binom{n}{k} = \frac{n \cdot \ldots \cdot (n-k+1)}{k!} \leq \frac{n^{k}}{k!} = \frac{n^{k} \cdot k^{k}}{k^{k} \cdot k!}$$

$$= \left(\frac{n}{k}\right)^{k} \cdot \frac{k^{k}}{k!} \leq \left(\frac{en}{k}\right)^{k}$$
The set of the set o

# 7.6 Skip Lists

Let  $E_{z,k}$  denote the event that a search path is of length z (number of edges) but does not visit a list above  $L_k$ .

In particular, this means that during the construction in the backward analysis we see at most k heads (i.e., coin flips that tell you to go up) in z trials.

5000	EADS
	© Ernst Mayr, Harald Räcke

7.6 Skip Lists

217

# 7.6 Skip Lists

So far we fixed  $k = \gamma \log n$ ,  $\gamma \ge 1$ , and  $z = 7\alpha \gamma \log n$ ,  $\alpha \ge 1$ .

This means that a search path of length  $\Omega(\log n)$  visits a list on a level  $\Omega(\log n)$ , w.h.p.

Let  $A_{k+1}$  denote the event that the list  $L_{k+1}$  is non-empty. Then

 $\Pr[A_{k+1}] \le n2^{-(k+1)} \le n^{-(\gamma-1)}$ .

For the search to take at least  $z = 7\alpha \gamma \log n$  steps either the event  $E_{z,k}$  or the even  $A_{k+1}$  must hold. Hence,

 $\begin{aligned} &\Pr[\text{search requires } z \text{ steps}] \leq \Pr[E_{z,k}] + \Pr[A_{k+1}] \\ &\leq n^{-\alpha} + n^{-(\gamma-1)} \end{aligned}$ 

This means, the search requires at most *z* steps, w. h. p.

# 7.6 Skip Lists

 $\Pr[E_{z,k}] \leq \Pr[\text{at most } k \text{ heads in } z \text{ trials}]$ 

$$\leq \binom{z}{k} 2^{-(z-k)} \leq \left(\frac{ez}{k}\right)^k 2^{-(z-k)} \leq \left(\frac{2ez}{k}\right)^k 2^{-z}$$

choosing  $k = \gamma \log n$  with  $\gamma \ge 1$  and  $z = (\beta + \alpha)\gamma \log n$ 

$$\leq \left(\frac{2ez}{k}\right)^{k} 2^{-\beta k} \cdot n^{-\gamma \alpha} \leq \left(\frac{2ez}{2^{\beta}k}\right)^{k} \cdot n^{-\alpha}$$
$$\leq \left(\frac{2e(\beta + \alpha)}{2^{\beta}}\right)^{k} n^{-\alpha}$$

now choosing 
$$\beta = 6\alpha$$
 gives

 $\leq$ 

$$\left(\frac{42\alpha}{64^{\alpha}}\right)^k n^{-\alpha} \le n^{-\alpha}$$

for  $\alpha \ge 1$ .

🛛 🕒 🖓 🕼 Ernst Mayr, Harald Räcke		218

# 7.7 Hashing

Dictionary:

- ► *S*.insert(*x*): Insert an element *x*.
- ► *S*.delete(*x*): Delete the element pointed to by *x*.
- S.search(k): Return a pointer to an element *e* with key[*e*] = k in S if it exists; otherwise return null.

So far we have implemented the search for a key by carefully choosing split-elements.

Then the memory location of an object x with key k is determined by successively comparing k to split-elements.

Hashing tries to directly compute the memory location from the given key. The goal is to have constant search time.

EADS	7.7 Hashing	
🛛 🕒 🛛 🖉 © Ernst Mayr, Harald Räcke		220

# Direct Addressing

Ideally the hash function maps all keys to different memory locations.

This special case is known as Direct Addressing. It is usually very unrealistic as the universe of keys typically is quite large, and in particular larger than the available memory.

הם הי	EADS	
	© Ernst Mayr, Harald	Räcke

222

# 7.7 Hashing

#### Definitions:

- Universe U of keys, e.g.,  $U \subseteq \mathbb{N}_0$ . U very large.
- Set  $S \subseteq U$  of keys,  $|S| = m \le |U|$ .
- Array  $T[0, \ldots, n-1]$  hash-table.
- Hash function  $h: U \rightarrow [0, \dots, n-1]$ .

#### The hash-function *h* should fulfill:

- Fast to evaluate.
- Small storage requirement.
- Good distribution of elements over the whole table.

EADS	7.7 Hashing
🛛 🕒 🛛 🖉 Ernst Mayr, Harald Räcke	

# Perfect Hashing

Suppose that we know the set S of actual keys (no insert/no delete). Then we may want to design a simple hash-function that maps all these keys to different memory locations.

Such a hash function h is called a perfect hash function for set S.

EADS © Ernst Mayr, Harald Räcke

# Collisions

If we do not know the keys in advance, the best we can hope for is that the hash function distributes keys evenly across the table.

#### **Problem: Collisions**

Usually the universe U is much larger than the table-size n.

Hence, there may be two elements  $k_1, k_2$  from the set *S* that map to the same memory location (i.e.,  $h(k_1) = h(k_2)$ ). This is called a collision.

EADS © Ernst Mayr, Harald Räcke 7.7 Hashing

224

#### Collisions

#### **Proof.**

Let  $A_{m,n}$  denote the event that inserting m keys into a table of size n does not generate a collision. Then

$$\Pr[A_{m,n}] = \prod_{\ell=1}^{m} \frac{n-\ell+1}{n} = \prod_{j=0}^{m-1} \left(1 - \frac{j}{n}\right)$$
$$\leq \prod_{j=0}^{m-1} e^{-j/n} = e^{-\sum_{j=0}^{m-1} \frac{j}{n}} = e^{-\frac{m(m-1)}{2n}}$$

Here the first equality follows since the  $\ell$ -th element that is hashed has a probability of  $\frac{n-\ell+1}{n}$  to not generate a collision under the condition that the previous elements did not induce collisions.

EADS 🛛 🗌 😨 Ernst Mayr, Harald Räcke

226

# Collisions

Typically, collisions do not appear once the size of the set *S* of actual keys gets close to *n*, but already when  $|S| \ge \omega(\sqrt{n})$ .

#### Lemma 12

The probability of having a collision when hashing m elements into a table of size n under uniform hashing is at least

 $1 - e^{-\frac{m(m-1)}{2n}} \approx 1 - e^{-\frac{m^2}{2n}}$ .

#### Uniform hashing:

Choose a hash function uniformly at random from all functions  $f: U \rightarrow [0, ..., n-1].$ 

	7.7 Hashing	
🛛 💾 🖓 🖉 Ernst Mayr, Harald Räcke		225

# **Resolving Collisions**

The methods for dealing with collisions can be classified into the two main types

- open addressing, aka. closed hashing
- hashing with chaining, aka. closed addressing, open hashing.

There are applications e.g. computer chess where you do not resolve collisions at all.

EADS © Ernst Mayr, Harald Räcke 7.7 Hashing

228

# Hashing with Chaining

Arrange elements that map to the same position in a linear list.

- Access: compute h(x) and search list for key[x].
- Insert: insert at the front of the list.

# Hashing with Chaining

The time required for an unsuccessful search is 1 plus the length of the list that is examined. The average length of a list is  $\alpha = \frac{m}{n}$ . Hence, if *A* is the collision resolving strategy "Hashing with Chaining" we have

$$A^- = 1 + \alpha \; .$$

# Hashing with Chaining

For a successful search observe that we do **not** choose a list at random, but we consider a random key k in the hash-table and ask for the search-time for k.

This is 1 plus the number of elements that lie before k in k's list.

Let  $k_\ell$  denote the  $\ell$ -th key inserted into the table.

Let for two keys  $k_i$  and  $k_j$ ,  $X_{ij}$  denote the indicator variable for the event that  $k_i$  and  $k_j$  hash to the same position. Clearly,  $\Pr[X_{ij} = 1] = 1/n$  for uniform hashing.

The expected successful search cost is

keys before  $k_i$  $\mathbf{E}\left[\frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}X_{ij}\right)\right]$ 

EADS © Ernst Mayr, Harald Räcke 7.7 Hashing

# Hashing with Chaining

#### **Disadvantages:**

- pointers increase memory requirements
- pointers may lead to bad cache efficiency

#### Advantages:

- no à priori limit on the number of elements
- deletion can be implemented efficiently
- by using balanced trees instead of linked list one can also obtain worst-case guarantees.

# Hashing with Chaining

$$\begin{split} \mathbf{E}\left[\frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}X_{ij}\right)\right] &= \frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}\mathbf{E}\left[X_{ij}\right]\right)\\ &= \frac{1}{m}\sum_{i=1}^{m}\left(1+\sum_{j=i+1}^{m}\frac{1}{n}\right)\\ &= 1+\frac{1}{mn}\sum_{i=1}^{m}(m-i)\\ &= 1+\frac{1}{mn}\left(m^{2}-\frac{m(m+1)}{2}\right)\\ &= 1+\frac{m-1}{2n} = 1+\frac{\alpha}{2}-\frac{\alpha}{2m} \end{split}$$
  
Hence, the expected cost for a successful search is  $A^{+} \leq 1+\frac{\alpha}{2}$ .

	7.7 Hashing	
🛛 💾 🛛 🖉 Ernst Mayr, Harald Räcke		233

# **Open Addressing**

EADS

© Ernst Mayr, Harald Räcke

All objects are stored in the table itself.

Define a function h(k, j) that determines the table-position to be examined in the *j*-th step. The values  $h(k, 0), \ldots, h(k, n - 1)$  must form a permutation of  $0, \ldots, n - 1$ .

**Search**(k): Try position h(k, 0); if it is empty your search fails; otw. continue with h(k, 1), h(k, 2), ....

**Insert**(x): Search until you find an empty slot; insert your element there. If your search reaches h(k, n - 1), and this slot is non-empty then your table is full.

# **Open Addressing**

Choices for h(k, j):

- Linear probing:  $h(k,i) = h(k) + i \mod n$ (sometimes:  $h(k, i) = h(k) + ci \mod n$ ).
- Quadratic probing:  $h(k,i) = h(k) + c_1 i + c_2 i^2 \mod n.$
- Double hashing:  $h(k, i) = h_1(k) + ih_2(k) \mod n.$

For quadratic probing and double hashing one has to ensure that the search covers all positions in the table (i.e., for double hashing  $h_2(k)$  must be relatively prime to *n* (teilerfremd); for quadratic probing  $c_1$  and  $c_2$  have to be chosen carefully).

	7.7 Hashing
🛛 🕒 🖓 🖉 Ernst Mayr. Harald Räcke	

# **Quadratic Probing**

- Not as cache-efficient as Linear Probing.
- Secondary clustering: caused by the fact that all keys mapped to the same position have the same probe sequence.

#### Lemma 14

Let Q be the method of quadratic probing for resolving collisions:

$$Q^+ \approx 1 + \ln\left(\frac{1}{1-\alpha}\right) - \frac{\alpha}{2}$$
  
 $Q^- \approx \frac{1}{1-\alpha} + \ln\left(\frac{1}{1-\alpha}\right) - \alpha$ 

החוחר	EADS	
	© Ernst Mayr, Harald	Räcke

238

236

# **Linear Probing**

- Advantage: Cache-efficiency. The new probe position is very likely to be in the cache.
- Disadvantage: Primary clustering. Long sequences of occupied table-positions get longer as they have a larger probability to be hit. Furthermore, they can merge forming larger sequences.

#### Lemma 13

Let *L* be the method of linear probing for resolving collisions:

$$L^+ \approx \frac{1}{2} \left( 1 + \frac{1}{1 - \alpha} \right)$$

$$L^{-} \approx \frac{1}{2} \left( 1 + \frac{1}{(1-\alpha)^2} \right)$$

# Analysis of Idealized Open Address Hashing

The number of probes in a successful search for k is equal to the number of probes made in an unsuccessful search for k at the time that k is inserted.

Let *k* be the *i* + 1-st element. The expected time for a search for *k* is at most  $\frac{1}{1-i/n} = \frac{n}{n-i}$ .

#### **Analysis of Idealized Open Address Hashing**

#### **Deletions in Hashtables**

- Simply removing a key might interrupt the probe sequence of other keys which then cannot be found anymore.
- One can delete an element by replacing it with a deleted-marker.
  - During an insertion if a deleted-marker is encountered an element can be inserted there.
  - During a search a deleted-marker must not be used to terminate the probe sequence.
- The table could fill up with deleted-markers leading to bad performance.
- ► If a table contains many deleted-markers (linear fraction of the keys) one can rehash the whole table and amortize the cost for this rehash against the cost for the deletions.

#### EADS U]UU©Ernst Mayr, Harald Räcke

249

#### **Deletions in Hashtables**

#### How do we delete in a hash-table?

- For hashing with chaining this is not a problem. Simply search for the key, and delete the item in the corresponding list.
- For open addressing this is difficult.

	7.7 Hasning

7.7 Hashing

251

#### Universal Hashing

#### **Definition 16**

A class  $\mathcal{H}$  of hash-functions from the universe U into the set  $\{0, \ldots, n-1\}$  is called universal if for all  $u_1, u_2 \in U$  with  $u_1 \neq u_2$ 

$$\Pr[h(u_1) = h(u_2)] \le \frac{1}{n}$$

where the probability is w.r.t. the choice of a random hash-function from set  $\mathcal{H}$ .

Note that this means that the probability of a collision between two arbitrary elements is at most  $\frac{1}{n}$ .

#### **Universal Hashing**

Regardless, of the choice of hash-function there is always an input (a set of keys) that has a very poor worst-case behaviour.

Therefore, so far we assumed that the hash-function is random so that regardless of the input the average case behaviour is good.

However, the assumption of uniform hashing that h is chosen randomly from all functions  $f: U \rightarrow [0, ..., n-1]$  is clearly unrealistic as there are  $n^{|U|}$  such functions. Even writing down such a function would take  $|U| \log n$  bits.

Universal hashing tries to define a set  $\mathcal{H}$  of functions that is much smaller but still leads to good average case behaviour when selecting a hash-function uniformly at random from  $\mathcal{H}$ .

EADS © Ernst Mayr, Harald Räcke 7.7 Hashing

252

#### Universal Hashing

#### **Definition 17**

A class  $\mathcal{H}$  of hash-functions from the universe U into the set  $\{0, \ldots, n-1\}$  is called 2-independent (pairwise independent) if the following two conditions hold

- ▶ For any key  $u \in U$ , and  $t \in \{0, ..., n-1\}$   $\Pr[h(u) = t] = \frac{1}{n}$ , i.e., a key is distributed uniformly within the hash-table.
- For all u<sub>1</sub>, u<sub>2</sub> ∈ U with u<sub>1</sub> ≠ u<sub>2</sub>, and for any two hash-positions t<sub>1</sub>, t<sub>2</sub>:

$$\Pr[h(u_1) = t_1 \wedge h(u_2) = t_2] \le \frac{1}{n^2} .$$

This requirement clearly implies a universal hash-function.

EADS © Ernst Mayr, Harald Räcke

#### **Definition 18**

A class  $\mathcal{H}$  of hash-functions from the universe U into the set  $\{0, \ldots, n-1\}$  is called *k*-independent if for any choice of  $\ell \leq k$  distinct keys  $u_1, \ldots, u_\ell \in U$ , and for any set of  $\ell$  not necessarily distinct hash-positions  $t_1, \ldots, t_\ell$ :

 $\Pr[h(u_1) = t_1 \wedge \cdots \wedge h(u_\ell) = t_\ell] \leq \frac{1}{n^\ell} ,$ 

where the probability is w.r.t. the choice of a random hash-function from set  $\mathcal{H}$ .

EADS © Ernst Mayr, Harald Räcke 7.7 Hashing

#### **Universal Hashing**

Let  $U := \{0, ..., p - 1\}$  for a prime p. Let  $\mathbb{Z}_p := \{0, ..., p - 1\}$ , and let  $\mathbb{Z}_p^* := \{1, ..., p - 1\}$  denote the set of invertible elements in  $\mathbb{Z}_p$ .

Define

 $h_{a,b}(x) := (ax + b \mod p) \mod n$

7.7 Hashing

#### **Universal Hashing**

#### **Definition 19**

A class  $\mathcal{H}$  of hash-functions from the universe U into the set  $\{0, \ldots, n-1\}$  is called  $(\mu, k)$ -independent if for any choice of  $\ell \leq k$  distinct keys  $u_1, \ldots, u_\ell \in U$ , and for any set of  $\ell$  not necessarily distinct hash-positions  $t_1, \ldots, t_\ell$ :

$$\Pr[h(u_1) = t_1 \wedge \cdots \wedge h(u_\ell) = t_\ell] \leq \frac{\mu}{n^\ell} ,$$

7.7 Hashing

where the probability is w. r. t. the choice of a random hash-function from set  $\mathcal{H}$ .

EADS © Ernst Mayr, Harald Räcke

256

#### **Universal Hashing**

#### Proof.

255

257

Let  $x, y \in U$  be two distinct keys. We have to show that the probability of a collision is only 1/n.

 $\bullet \ ax + b \not\equiv ay + b \pmod{p}$ 

If  $x \neq y$  then  $(x - y) \not\equiv 0 \pmod{p}$ .

Multiplying with  $a \not\equiv 0 \pmod{p}$  gives

 $a(x-y) \not\equiv 0 \pmod{p}$ 

where we use that  $\mathbb{Z}_p$  is a field (Körper) and, hence, has no zero divisors (nullteilerfrei).

EADS ©Ernst Mayr, Harald Räcke

The hash-function does not generate collisions before the (mod *n*)-operation. Furthermore, every choice (*a*, *b*) is mapped to a different pair (*t<sub>x</sub>*, *t<sub>y</sub>*) with *t<sub>x</sub>* := *ax* + *b* and *t<sub>y</sub>* := *ay* + *b*.

This holds because we can compute a and b when given  $t_x$  and  $t_y$ :

$t_x \equiv ax + b$	$(\mod p)$
$t_{\mathcal{Y}} \equiv a \mathcal{Y} + b$	$(\mod p)$
$t_x - t_y \equiv a(x - y)$	$\pmod{p}$
$t_{\mathcal{Y}} \equiv a \mathcal{Y} + b$	$(\mod p)$
$a \equiv (t_x - t_y)(x - y)^{-1}$	$(\mod p)$
$b \equiv t_{\mathcal{Y}} - a \mathcal{Y}$	$(\mod p)$

#### **Universal Hashing**

As  $t_{\gamma} \neq t_{\chi}$  there are

$$\left\lceil \frac{p}{n} \right\rceil - 1 \le \frac{p}{n} + \frac{n-1}{n} - 1 \le \frac{p-1}{n}$$

7.7 Hashing

possibilities for choosing  $t_{\mathcal{Y}}$  such that the final hash-value creates a collision.

This happens with probability at most  $\frac{1}{n}$ .

	EADS
<u> </u>	© Ernst Mayr, Harald Räcke

261

#### **Universal Hashing**

There is a one-to-one correspondence between hash-functions (pairs (a, b),  $a \neq 0$ ) and pairs  $(t_x, t_y)$ ,  $t_x \neq t_y$ .

Therefore, we can view the first step (before the mod *n*-operation) as choosing a pair  $(t_x, t_y)$ ,  $t_x \neq t_y$  uniformly at random.

What happens when we do the mod n operation?

Fix a value  $t_x$ . There are p - 1 possible values for choosing  $t_y$ .

From the range 0, ..., p - 1 the values  $t_x, t_x + n, t_x + 2n, ...$  map to  $t_x$  after the modulo-operation. These are at most  $\lceil p/n \rceil$  values.

EADS 7.7 Hashing © Ernst Mayr, Harald Räcke

#### Universal Hashing

It is also possible to show that  ${\mathcal H}$  is an (almost) pairwise independent class of hash-functions.

$$\frac{\left\lfloor \frac{p}{n} \right\rfloor^2}{p(p-1)} \leq \Pr_{t_x \neq t_y \in \mathbb{Z}_p^2} \left[ \begin{array}{c} t_x \bmod n = h_1 \\ t_y \bmod n = h_2 \end{array} \right] \leq \frac{\left\lceil \frac{p}{n} \right\rceil^2}{p(p-1)}$$

Note that the middle is the probability that  $h(x) = h_1$  and  $h(y) = h_2$ . The total number of choices for  $(t_x, t_y)$  is p(p-1). The number of choices for  $t_x$   $(t_y)$  such that  $t_x \mod n = h_1$  $(t_y \mod n = h_2)$  lies between  $\lfloor \frac{p}{n} \rfloor$  and  $\lceil \frac{p}{n} \rceil$ .

EADS © Ernst Mayr, Harald Räcke

**Definition 21** Let  $d \in \mathbb{N}$ ;  $q \ge (d + 1)n$  be a prime; and let  $\bar{a} \in \{0, \dots, q-1\}^{d+1}$ . Define for  $x \in \{0, \dots, q-1\}$  $h_{\tilde{a}}(x) := \left(\sum_{i=0}^{d} a_i x^i \mod q\right) \mod n$ . Let  $\mathcal{H}_n^d := \{h_{\bar{a}} \mid \bar{a} \in \{0, \dots, q-1\}^{d+1}\}$ . The class  $\mathcal{H}_n^d$  is (e, d+1)-independent. Note that in the previous case we had d = 1 and chose  $a_d \neq 0$ . EADS © Ernst Mayr, Harald Räcke EADS 7.7 Hashing

#### **Universal Hashing**

Fix  $\ell \leq d+1$ ; let  $x_1, \ldots, x_\ell \in \{0, \ldots, q-1\}$  be keys, and let  $t_1, \ldots, t_\ell$  denote the corresponding hash-function values.

Let  $A^{\ell} = \{h_{\bar{a}} \in \mathcal{H} \mid h_{\bar{a}}(x_i) = t_i \text{ for all } i \in \{1, \dots, \ell\}\}$ Then

 $h_{\bar{a}} \in A^{\ell} \Leftrightarrow h_{\bar{a}} = f_{\bar{a}} \mod n$  and

$$f_{\bar{a}}(x_i) \in \underbrace{\{t_i + \alpha \cdot n \mid \alpha \in \{0, \dots, \lceil \frac{q}{n} \rceil - 1\}\}}_{=:B_i}$$

In order to obtain the cardinality of  $A^{\ell}$  we choose our polynomial by fixing d + 1 points.  $A^{\ell}$  denotes the set of hash-We first fix the values for inputs  $x_1, \ldots, x_\ell$ . functions such that every  $x_i$ hits its pre-defined position We have t<sub>i</sub>.  $|B_1| \cdot \ldots \cdot |B_\ell|$ • B<sub>i</sub> is the set of positions that  $f_{\bar{a}}$  can hit so that  $h_{\bar{a}}$  still hits possibilities to do this (so that  $h_{\bar{a}}(x_i) = t_i$ ). t<sub>i</sub>.

#### **Universal Hashing**

For the coefficients  $\bar{a} \in \{0, \dots, q-1\}^{d+1}$  let  $f_{\bar{a}}$  denote the polynomial

$$f_{\tilde{a}}(x) = \left(\sum_{i=0}^{a} a_i x^i\right) \mod q$$

The polynomial is defined by d + 1 distinct points.

EADS © Ernst Mayr, Harald Räcke

263

7.7 Hashing

264

266

#### **Universal Hashing** Now, we choose $d - \ell + 1$ other inputs and choose their value arbitrarily. We have $q^{d-\ell+1}$ possibilities to do this. Therefore we have $|B_1|\cdot\ldots\cdot|B_\ell|\cdot q^{d-\ell+1} \leq \lceil \frac{q}{n}\rceil^\ell \cdot q^{d-\ell+1}$ possibilities to choose $\bar{a}$ such that $h_{\bar{a}} \in A_{\ell}$ . 7.7 Hashing © Ernst Mayr, Harald Räcke

Therefore the probability of choosing  $h_{\tilde{a}}$  from  $A_{\ell}$  is only

$$\begin{split} \frac{\lceil \frac{q}{n} \rceil^{\ell} \cdot q^{d-\ell+1}}{q^{d+1}} &\leq \frac{(\frac{q+n}{n})^{\ell}}{q^{\ell}} \leq \left(\frac{q+n}{q}\right)^{\ell} \cdot \frac{1}{n^{\ell}} \\ &\leq \left(1 + \frac{1}{\ell}\right)^{\ell} \cdot \frac{1}{n^{\ell}} \leq \frac{e}{n^{\ell}} \end{split}$$

This shows that the  $\mathcal{H}$  is (e, d + 1)-universal.

The last step followed from  $q \ge (d+1)n$ , and  $\ell \le d+1$ .

EADS © Ernst Mayr, Harald Räcke

7.7 Hashing

#### **Perfect Hashing**

Let m = |S|. We could simply choose the hash-table size very large so that we don't get any collisions.

Using a universal hash-function the expected number of collisions is

 $\mathbf{E}[\texttt{\#Collisions}] = \binom{m}{2} \cdot \frac{1}{n} \ .$ 

If we choose  $n = m^2$  the expected number of collisions is strictly less than  $\frac{1}{2}$ .

Can we get an upper bound on the probability of having collisions?

The probability of having 1 or more collisions can be at most  $\frac{1}{2}$  as otherwise the expectation would be larger than  $\frac{1}{2}$ .

267

#### Perfect Hashing

Suppose that we **know** the set S of actual keys (no insert/no delete). Then we may want to design a **simple** hash-function that maps all these keys to different memory locations.

#### Perfect Hashing

We can find such a hash-function by a few trials.

However, a hash-table size of  $n = m^2$  is very very high.

We construct a two-level scheme. We first use a hash-function that maps elements from S to m buckets.

Let  $m_j$  denote the number of items that are hashed to the *j*-th bucket. For each bucket we choose a second hash-function that maps the elements of the bucket into a table of size  $m_j^2$ . The second function can be chosen such that all elements are mapped to different locations.

#### **Perfect Hashing**

We need only  $\mathcal{O}(m)$  time to construct a hash-function *h* with  $\sum_{i} m_{i}^{2} = O(4m)$ , because with probability at least 1/2 a random function from a universal family will have this property.

Then we construct a hash-table  $h_i$  for every bucket. This takes expected time  $\mathcal{O}(m_i)$  for every bucket. A random function  $h_i$  is collision-free with probability at least 1/2. We need  $\mathcal{O}(m_i)$  to test this.

We only need that the hash-functions are chosen from a universal family!!!

#### **Perfect Hashing**

The total memory that is required by all hash-tables is  $\mathcal{O}(\sum_{i} m_{i}^{2})$ . Note that  $m_{j}$  is a random variable.

$$E\left[\sum_{j} m_{j}^{2}\right] = E\left[2\sum_{j} \binom{m_{j}}{2} + \sum_{j} m_{j}\right]$$
$$= 2E\left[\sum_{j} \binom{m_{j}}{2}\right] + E\left[\sum_{j} m_{j}\right]$$

The first expectation is simply the expected number of collisions, for the first level. Since we use universal hashing we have

$$=2\binom{m}{2}\frac{1}{m}+m=2m-1$$

EADS © Ernst Mayr, Harald Räcke

7.7 Hashing

#### **Cuckoo Hashing**

#### Goal:

nn EADS

© Ernst Mayr, Harald Räcke

Try to generate a hash-table with constant worst-case search time in a dynamic scenario.

- ▶ Two hash-tables  $T_1[0, \ldots, n-1]$  and  $T_2[0, \ldots, n-1]$ , with hash-functions  $h_1$ , and  $h_2$ .
- An object x is either stored at location  $T_1[h_1(x)]$  or  $T_2[h_2(x)].$
- A search clearly takes constant time if the above constraint is met.

- We call one iteration through the while-loop a step of the algorithm.
- We call a sequence of iterations through the while-loop without the termination condition becoming true a phase of the algorithm.
- We say a phase is successful if it is not terminated by the maxstep-condition, but the while loop is left because x =null.

#### **Cuckoo Hashing**

Algorithm 17 Cuckoo-Insert(x)
1: if $T_1[h_1(x)] = x \lor T_2[h_2(x)] = x$ then return
2: steps ← 1
3: while steps ≤ maxsteps do
4: exchange x and $T_1[h_1(x)]$
5: if $x = $ null then return
6: exchange x and $T_2[h_2(x)]$
7: if $x = $ null then return
8: steps $\leftarrow$ steps $+1$
9: rehash() // change hash-functions; rehash everything
10: Cuckoo-Insert( <i>x</i> )
EADS 7.7 Hashing

A cycle-structure is active if for every key  $x_{\ell}$  (linking a cell  $p_i$ from  $T_1$  and a cell  $p_i$  from  $T_2$ ) we have

> and  $h_2(x_\ell) = p_i$  $h_1(x_\ell) = p_i$

#### **Observation:**

If during a phase the insert-procedure runs into a cycle there must exist an active cycle structure of size  $s \ge 3$ .

- The leftmost cell is "linked forward" to some cell on the right.
- The rightmost cell is "linked backward" to a cell on the left.
- One link represents key x; this is where the counting starts.

	7.7 Hashing	
UUUC © Ernst Mayr, Harald Räcke		280

#### **Cuckoo Hashing**

What is the probability that all keys in a cycle-structure of size *s* correctly map into their  $T_1$ -cell?

This probability is at most  $\frac{\mu}{n^s}$  since  $h_1$  is a  $(\mu, s)$ -independent hash-function.

What is the probability that all keys in the cycle-structure of size s correctly map into their  $T_2$ -cell?

This probability is at most  $\frac{\mu}{n^s}$  since  $h_2$  is a  $(\mu, s)$ -independent hash-function.

These events are independet.

EADS

7.7 Hashing

#### **Cuckoo Hashing**

The number of cycle-structures of size s is at most

 $s^3 \cdot n^{s-1} \cdot m^{s-1}$  .

- There are at most s<sup>2</sup> possibilities where to attach the forward and backward links.
- There are at most s possibilities to choose where to place key x.
- There are m<sup>s-1</sup> possibilities to choose the keys apart from x.
- There are  $n^{s-1}$  possibilities to choose the cells.

	7.7 Hashing	
UUUC © Ernst Mayr, Harald Räcke		284

Taking  $x_1 \rightarrow \cdots \rightarrow x_i$  twice, and  $x_1 \rightarrow x_{i+1} \rightarrow \dots x_j$  once gives  $2i + (j - i + 1) = i + j + 1 \ge p + 2$  keys. Hence, one of the sequences contains at least (p + 2)/3 keys.

#### Proof.

Let i be the number of keys (including x) that we see before the first repeated key. Let j denote the total number of distinct keys.

The sequence is of the form:

 $x = x_1 \rightarrow x_2 \rightarrow \cdots \rightarrow x_i \rightarrow x_r \rightarrow x_{r-1} \rightarrow \cdots \rightarrow x_1 \rightarrow x_{i+1} \rightarrow \cdots \rightarrow x_j$ 

As  $r \leq i - 1$  the length *p* of the sequence is

 $p=i+r+(j-i)\leq i+j-1 \ .$ 

Either sub-sequence  $x_1 \rightarrow x_2 \rightarrow \cdots \rightarrow x_i$  or sub-sequence  $x_1 \rightarrow x_{i+1} \rightarrow \cdots \rightarrow x_j$  has at least  $\frac{p+2}{3}$  elements.

EADS 7.7 Hashing □|||||| © Ernst Mayr, Harald Räcke

289

#### Cuckoo Hashing

Consider the sequence of not necessarily distinct keys starting with x in the order that they are visited during the phase.

#### Lemma 22

If the sequence is of length p then there exists a sub-sequence of at least  $\frac{p+2}{3}$  keys starting with x of distinct keys.

רח (הה) EADS	7.7 Hashing	
🛛 💾 🛛 🖉 © Ernst Mayr, Harald Räcke		288

A path-structure is active if for every key  $x_{\ell}$  (linking a cell  $p_i$  from  $T_1$  and a cell  $p_j$  from  $T_2$ ) we have

 $h_1(x_{\ell}) = p_i$  and  $h_2(x_{\ell}) = p_j$ 

**Observation:** 

If a phase takes at least t steps without running into a cycle there must exist an active path-structure of size (2t + 2)/3.

Note that we count complete steps. A search that touches 2t or 2t + 1 keys takes t steps.

EADS © Ernst Mayr, Harald Räcke 7.7 Hashing

291

293

#### **Cuckoo Hashing**

We choose maxsteps  $\ge 3\ell/2 + 2$ . Then the probability that a phase terminates unsuccessfully without running into a cycle is at most

Pr[unsuccessful | no cycle]

 $\leq \Pr[\exists active path-structure of size at least \frac{2maxsteps-1}{3}]$ 

 $\leq \Pr[\exists active path-structure of size at least \ell + 1]$ 

 $\leq \Pr[\exists active path-structure of size exactly \ell + 1]$ 

$$\leq 2\mu^2 \Big(\frac{1}{1+\epsilon}\Big)^\ell \leq \frac{1}{m^2}$$

by choosing  $\ell \geq \log{\left(\frac{1}{2\mu^2m^2}\right)}/\log{\left(\frac{1}{1+\epsilon}\right)} = \log{(2\mu^2m^2)}/\log{(1+\epsilon)}$ 

This gives maxsteps =  $\Theta(\log m)$ . Note that the existence of a path structure of size larger than *s* implies the existence of a path structure of size exactly *s*.

#### **Cuckoo Hashing**

The probability that a given path-structure of size *s* is active is at most  $\frac{\mu^2}{n^{2s}}$ .

The probability that there exists an active path-structure of size s is at most

Cuckoo Hashing	
So far we estimated	
$\Pr[cycle] \leq \mathcal{O}$	$\left(\frac{1}{m^2}\right)$
and Pr[unsuccessful   no cy	$vcle] \le \mathcal{O}\Big(\frac{1}{m^2}\Big)$
Observe that	
Pr[successful] = Pr[no cycle] - P	r[unsuccessful   no cycle]
$\geq c \cdot \Pr[no cycle]$	
for a suitable constant $c > 0$ .	This is a very weak (and trivial) statement but still sufficient for our asymptotic analysis.
EADS 7.7 Hashing © Ernst Mayr, Harald Räcke	294

The expected number of complete steps in the successful phase of an insert operation is:

E[number of steps | phase successful]

 $=\sum_{t\geq 1} \Pr[$ ast t steps | phase successful]

We have

 $\Pr[\text{search at least } t \text{ steps } | \text{successful}]$ 

#### **Cuckoo Hashing**

EADS

∐|∐∐©Ernst Mayr, Harald Räcke

A phase that is not successful induces cost  $\mathcal{O}(m)$  for doing a complete rehash (this dominates the cost for the steps in the phase).

The probability that a phase is not successful is  $p = O(1/m^2)$ (probability  $O(1/m^2)$  of running into a cycle and probability  $\mathcal{O}(1/m^2)$  of reaching maxsteps without running into a cycle).

7.7 Hashing

The expected number of unsuccessful phases is  $\sum_{i\geq 1} p^i = \frac{1}{1-p} - 1 = \frac{p}{1-p} = \mathcal{O}(p).$ 

Therefore the expected cost for re-hashes is  $\mathcal{O}(m) \cdot \mathcal{O}(p) = \mathcal{O}(1/m).$ 

$$\frac{Pr[search at least t steps | successful]}{Pr[search at least t steps \land successful]/Pr[}$$

$$] = \frac{\Pr[A \land B]}{\Pr[B]}$$

297

7.7 Hashing

296

#### **Cuckoo Hashing**

Hence,

E[number of steps | phase successful]

$$\leq \frac{1}{c} \sum_{t \geq 1} \Pr[\text{search at least } t \text{ steps } | \text{ no cycle}]$$
  
$$\leq \frac{1}{c} \sum_{t \geq 1} 2\mu^2 \left(\frac{1}{1+\epsilon}\right)^{(2t-1)/3}$$
  
$$\leq \frac{2\mu^2 (1+\epsilon)^{2/3}}{c} \sum_{t \geq 0} \left(\frac{1}{(1+\epsilon)^{2/3}}\right)^t = \mathcal{O}(1) \ .$$

This means the expected cost for a successful phase is constant (even after accounting for the cost of the incomplete step that finishes the phase).

#### **Cuckoo Hashing**

EADS © Ernst Mayr, Harald Räcke

#### What kind of hash-functions do we need?

Since maxsteps is  $\Theta(\log m)$  the largest size of a path-structure or cycle-structure contains just  $\Theta(\log m)$  different keys.

Therefore, it is sufficient to have  $(\mu, \Theta(\log m))$ -independent hash-functions.

#### How do we make sure that $n \ge (1 + \epsilon)m$ ?

- Let  $\alpha := 1/(1 + \epsilon)$ .
- Keep track of the number of elements in the table. When  $m \ge \alpha n$  we double n and do a complete re-hash (table-expand).
- Whenever *m* drops below  $\alpha n/4$  we divide *n* by 2 and do a rehash (table-shrink).
- Note that right after a change in table-size we have  $m = \alpha n/2$ . In order for a table-expand to occur at least  $\alpha n/2$  insertions are required. Similar, for a table-shrink at least  $\alpha n/4$  deletions must occur.
- Therefore we can amortize the rehash cost after a change in table-size against the cost for insertions and deletions.

EADS © Ernst Mayr, Harald Räcke	7.7 Hashing
------------------------------------	-------------

#### Cuckoo Hashing

#### Lemma 23

*Cuckoo Hashing has an expected constant insert-time and a worst-case constant search-time.* 

Note that the above lemma only holds if the fill-factor (number of keys/total number of hash-table slots) is at most  $\frac{1}{2(1+\epsilon)}$ .

- **delete**(*h*): Swap with *x* and bubble up or sift-down. Time  $\mathcal{O}(\log n).$
- **build** $(x_1, \ldots, x_n)$ : Insert elements arbitrarily; then do sift-down operations starting with the lowest layer in the tree. Time  $\mathcal{O}(n)$ .

#### **Build Heap**

We can build a heap in linear time:

#### **Binary Heaps**

EADS

© Ernst Mayr, <u>Harald Räcke</u>

The standard implementation of binary heaps is via arrays. Let  $A[0,\ldots,n-1]$  be an array

- The parent of *i*-th element is at position  $\lfloor \frac{i-1}{2} \rfloor$ .
- The left child of *i*-th element is at position 2i + 1.
- The right child of *i*-th element is at position 2i + 2.

Finding the successor of x is much easier than in the description on the previous slide. Simply increase or decrease x.

The resulting binary heap is not addressable. The elements don't maintain their positions and therefore there are no stable handles.

#### 323

325

#### 8.2 Binomial Heaps

#### How do we implement trees with non-constant degree?

- The children of a node are arranged in a circular linked list.
- A child-pointer points to an arbitrary node within the list.
- A parent-pointer points to the parent node.
- Pointers x. left and x. right point to the left and right sibling of x (if x does not have siblings then x. left = x. right = x).

#### **8.2 Binomial Heaps**

- Given a pointer to a node x we can splice out the sub-tree rooted at x in constant time.
- $\blacktriangleright$  We can add a child-tree T to a node x in constant time if we are given a pointer to x and a pointer to the root of T.

	© Ernst Mavr. Harald Räcke

8.2 Binomial Heaps

#### **Binomial Heap: Merge**

Given the number n of keys to be stored in a binomial heap we can deduce the binomial trees that will be contained in the collection.

Let  $B_{k_1}$ ,  $B_{k_2}$ ,  $B_{k_3}$ ,  $k_i < k_{i+1}$  denote the binomial trees in the collection and recall that every tree may be contained at most once.

Then  $n = \sum_{i} 2^{k_i}$  must hold. But since the  $k_i$  are all distinct this means that the  $k_i$  define the non-zero bit-positions in the binary representation of *n*.

#### **Binomial Heap**

In a binomial heap the keys are arranged in a collection of binomial trees.

Every tree fulfills the heap-property

There is at most one tree for every dimension/order. For example the above heap contains trees  $B_0$ ,  $B_1$ , and  $B_4$ .

EADS © Ernst Mayr, Harald Räcke

**Binomial Heap** 

8.2 Binomial Heaps

#### Properties of a heap with *n* keys: • Let $n = b_d b_{d-1}, \dots, b_0$ denote binary representation of n. • The heap contains tree $B_i$ iff $b_i = 1$ .

327

- Hence, at most  $|\log n| + 1$  trees.
- The minimum must be contained in one of the roots.
- The height of the largest tree is at most  $\lfloor \log n \rfloor$ .
- The trees are stored in a single-linked list; ordered by dimension/size.

#### **Binomial Heap: Merge**

The merge-operation is instrumental for binomial heaps.

A merge is easy if we have two heaps with different binomial trees. We can simply merge the tree-lists.

Note that we do not just do a concatenation as we want to keep the trees in the list sorted according to size.

Otherwise, we cannot do this because the merged heap is not allowed to contain two trees of the same order.

Merging two trees of the same size: Add the tree with larger root-value as a child to the other tree.

For more trees the technique is analogous to binary addition.

החוח	EADS

8.3 Fibonacci Heaps

#### Potential Method

#### Introduce a potential for the data structure.

- $\Phi(D_i)$  is the potential after the *i*-th operation.
- Amortized cost of the *i*-th operation is

$$\hat{c}_i = c_i + \Phi(D_i) - \Phi(D_{i-1})$$

Show that  $\Phi(D_i) \ge \Phi(D_0)$ .

Then

338

340

$$\sum_{i=1}^{k} c_i \le \sum_{i=1}^{k} c_i + \Phi(D_k) - \Phi(D_0) = \sum_{i=1}^{k} \hat{c}_i$$

This means the amortized costs can be used to derive a bound on the total cost.

EADS	8.3 Fibonacci Heaps	
🛛 🛄 🖓 🕼 © Ernst Mayr, Harald Räcke		339

#### **Example: Binary Counter**

#### Incrementing a binary counter:

Consider a computational model where each bit-operation costs one time-unit.

Incrementing an *n*-bit binary counter may require to examine *n*-bits, and maybe change them.

#### Actual cost:

- Changing bit from 0 to 1: cost 1.
- Changing bit from 1 to 0: cost 1.
- Increment: cost is k + 1, where k is the number of consecutive ones in the least significant bit-positions (e.g. 001101 has k = 1).

EADS	8.3 Fibonacci Heaps	
🛛 🕒 🛛 🖉 © Ernst Mayr, Harald Räcke		342

#### 8.3 Fibonacci Heaps

Collection of trees that fulfill the heap property.

Structure is much more relaxed than binomial heaps.

#### **Example: Binary Counter**

Choose potential function  $\Phi(x) = k$ , where k denotes the number of ones in the binary representation of x.

#### Amortized cost:

• Changing bit from 0 to 1:

$$\hat{C}_{0\to 1} = C_{0\to 1} + \Delta \Phi = 1 + 1 \le 2 \ .$$

• Changing bit from 1 to 0:

$$\hat{C}_{1\to 0} = C_{1\to 0} + \Delta \Phi = 1-1 \le 0 \ .$$

• Increment: Let k denotes the number of consecutive ones in the least significant bit-positions. An increment involves k $(1 \rightarrow 0)$ -operations, and one  $(0 \rightarrow 1)$ -operation.

Hence, the amortized cost is  $k\hat{C}_{1\rightarrow 0} + \hat{C}_{0\rightarrow 1} \leq 2$ .

	8.3 Fibonacci Heaps	
🛛 🕒 🖯 © Ernst Mayr, Harald Räcke		343

#### The potential function:

- t(S) denotes the number of trees in the heap.
- m(S) denotes the number of marked nodes.
- We use the potential function  $\Phi(S) = t(S) + 2m(S)$ .

The potential is  $\Phi(S) = 5 + 2 \cdot 3 = 11$ .

 $D(\min)$  is the number of children of the node that stores the minimum.

351

- S. delete-min(x)
  - ► Delete minimum; add child-trees to heap; time: D(min) • O(1).
  - Update min-pointer; time:  $(t + D(\min)) \cdot O(1)$ .

• Consolidate root-list so that no roots have the same degree. Time  $t \cdot O(1)$  (see next slide).

|--|

#### 8.3 Fibonacci Heaps

 $D(\min)$  is the number of children of the node that stores the minimum.

#### S. delete-min(x)

- ► Delete minimum; add child-trees to heap; time: D(min) · O(1).
- Update min-pointer; time:  $(t + D(\min)) \cdot O(1)$ .

## 8.3 Fibonacci Heaps Consolidate:

# 8.3 Fibonacci Heaps Consolidate:

EADS © Ernst Mayr, Harald Räcke

8.3 Fibonacci Heaps

t and t' denote the number of trees before and after the delete-min() operation, respectively.  $D_n$  is an upper bound on the degree (i.e., number of children) of a tree node.

#### Actual cost for delete-min()

- At most  $D_n + t$  elements in root-list before consolidate.
- Actual cost for a delete-min is at most  $O(1) \cdot (D_n + t)$ . Hence, there exists  $c_1$  s.t. actual cost is at most  $c_1 \cdot (D_n + t)$ .

#### Amortized cost for delete-min()

- ▶  $t' \leq D_n + 1$  as degrees are different after consolidating.
- Therefore  $\Delta \Phi \leq D_n + 1 t$ ;
- We can pay  $c \cdot (t D_n 1)$  from the potential decrease.
- The amortized cost is

 $c_1 \cdot (D_n + t) - \frac{c}{c} \cdot (t - D_n - 1)$ 

$$\leq (c_1 + c)D_n + (c_1 - c)t + c \leq 2c(D_n + 1) \leq \mathcal{O}(D_n)$$

for  $c \geq c_1$  .

רח EADS	8.3 Fibonacci Heaps	
🛛 💾 🛛 🖉 © Ernst Mayr, Harald Räcke		353

#### 8.3 Fibonacci Heaps

If the input trees of the consolidation procedure are binomial trees (for example only singleton vertices) then the output will be a set of distinct binomial trees, and, hence, the Fibonacci heap will be (more or less) a Binomial heap right after the consolidation.

If we do not have delete or decrease-key operations then  $D_n \leq \log n$ .

EADS 8.3 Fibonacci Heaps © Ernst Mayr, Harald Räcke 354

#### Fibonacci Heaps: decrease-key(handle h, v)

#### Case 2: heap-property is violated, but parent is not marked

- Decrease key-value of element x reference by h.
- If the heap-property is violated, cut the parent edge of x, and make x into a root.
- Adjust min-pointers, if necessary.
- Mark the (previous) parent of *x* (unless it's a root).

	8.3 Fibonacci Heaps

#### Fibonacci Heaps: decrease-key(handle h, v)

#### Case 3: heap-property is violated, and parent is marked

- Decrease key-value of element *x* reference by *h*.
- Cut the parent edge of *x*, and make *x* into a root.
- Adjust min-pointers, if necessary.
- Continue cutting the parent until you arrive at an unmarked node.

	8.3 Fibonacci Heaps	
UUU © Ernst Mayr, Harald Räcke		355

#### Fibonacci Heaps: decrease-key(handle h, v)

#### Actual cost:

- Constant cost for decreasing the value.
- Constant cost for each of  $\ell$  cuts.
- Hence, cost is at most  $c_2 \cdot (\ell + 1)$ , for some constant  $c_2$ .

#### Amortized cost:

if  $C \geq C_2$ .

- $t' = t + \ell$ , as every cut creates one new root.
- $m' \le m (\ell 1) + 1 = m \ell + 2$ , since all but the first cut unmarks a node; the last cut may mark a node.
- $\Delta \Phi \le \ell + 2(-\ell + 2) = 4 \ell$
- Amortized cost is at most
- $c_2(\ell+1) + c(4-\ell) \le (c_2-c)\ell + 4c + c_2 = O(1), m \text{ and } m': \text{ number of } m' \le 0$

operation. m and m': number of marked nodes before and after operation.

357

t and t': number of trees before and after

EADS © Ernst Mayr, Harald Räcke	8.3 Fibonacci Heaps

## **8.3 Fibonacci Heaps** Lemma 25 Let x be a node with degree k and let $y_1, \ldots, y_k$ denote the children of x in the order that they were linked to x. Then $degree(y_i) \ge \begin{cases} 0 & \text{if } i = 1\\ i-2 & \text{if } i > 1 \end{cases}$ The marking process is very important for the proof of this lemma. It ensures that a node can have lost at most one child since the last time it became a non-root node. When losing a first child the node gets marked; when losing the second child it is cut from the parent and made into a root.

50.00	FADS

#### 359

#### **Delete node**

#### *H*.delete(*x*):

- decrease value of x to  $-\infty$ .
- delete-min.

#### Amortized cost: $\mathcal{O}(D_n)$

- $\mathcal{O}(1)$  for decrease-key.
- $\mathcal{O}(Dn)$  for delete-min.

EADS © Ernst Mayr, Harald Räcke	8.3 Fibonacci Heaps	358

#### 8.3 Fibonacci Heaps

#### Proof

- When y<sub>i</sub> was linked to x, at least y<sub>1</sub>,..., y<sub>i-1</sub> were already linked to x.
- ► Hence, at this time degree(x) ≥ i − 1, and therefore also degree(y<sub>i</sub>) ≥ i − 1 as the algorithm links nodes of equal degree only.
- Since, then  $y_i$  has lost at most one child.
- Therefore, degree( $y_i$ )  $\ge i 2$ .

- Let sk be the minimum possible size of a sub-tree rooted at a node of degree k that can occur in a Fibonacci heap.
- $s_k$  monotonically increases with k
- $s_0 = 1$  and  $s_1 = 2$ .

Let x be a degree k node of size  $s_k$  and let  $y_1, \ldots, y_k$  be its children.

#### 8.3 Fibonacci Heaps

#### **Definition 26**

Consider the following non-standard Fibonacci type sequence:

$$F_k = \begin{cases} 1 & \text{if } k = 0\\ 2 & \text{if } k = 1\\ F_{k-1} + F_{k-2} & \text{if } k \ge 2 \end{cases}$$

#### Facts:

1.  $F_k \ge \phi^k$ . 2. For  $k \ge 2$ :  $F_k = 2 + \sum_{i=0}^{k-2} F_i$ .

The above facts can be easily proved by induction. From this it follows that  $s_k \ge F_k \ge \phi^k$ , which gives that the maximum degree in a Fibonacci heap is logarithmic.

#### **List Implementation**

# List Implementation Running times: • find(x): constant • makeset(x): constant • union(x, y): O(n), where n denotes the number of elements contained in the set system.

#### List Implementation

#### List Implementation

#### Lemma 27

EADS © Ernst Mayr, Harald Räcke

The list implementation for the ADT union find fulfills the following amortized time bounds:

- find(x):  $\mathcal{O}(1)$ .
- makeset(x):  $\mathcal{O}(\log n)$ .
- union(x, y):  $\mathcal{O}(1)$ .

#### The Accounting Method for Amortized Time Bounds

- There is a bank account for every element in the data structure.
- Initially the balance on all accounts is zero.
- Whenever for an operation the amortized time bound exceeds the actual cost, the difference is credited to some bank accounts of elements involved.
- Whenever for an operation the actual cost exceeds the amortized time bound, the difference is charged to bank accounts of some of the elements involved.
- If we can find a charging scheme that guarantees that balances always stay positive the amortized time bounds are proven.

הם הי	EADS
	© Ernst Mayr, Harald Räcke

9 Union Find

371

#### **List Implementation**

**makeset**(x) : The actual cost is O(1). Due to the cost inflation the amortized cost is  $O(\log n)$ .

find(x) : For this operation we define the amortized cost and the actual cost to be the same. Hence, this operation does not change any accounts. Cost: O(1).

#### union(x, y):

- If  $S_x = S_y$  the cost is constant; no bank accounts change.
- Otw. the actual cost is  $\mathcal{O}(\min\{|S_{\chi}|, |S_{\mathcal{Y}}|\})$ .
- ► Assume wlog. that S<sub>x</sub> is the smaller set; let c denote the hidden constant, i.e., the actual cost is at most c · |S<sub>x</sub>|.
- Charge c to every element in set  $S_{\chi}$ .

#### **List Implementation**

- For an operation whose actual cost exceeds the amortized cost we charge the excess to the elements involved.
- ► In total we will charge at most O(log n) to an element (regardless of the request sequence).
- For each element a makeset operation occurs as the first operation involving this element.
- We inflate the amortized cost of the makeset-operation to  $\Theta(\log n)$ , i.e., at this point we fill the bank account of the element to  $\Theta(\log n)$ .
- Later operations charge the account but the balance never drops below zero.

EADS ©Ernst Mayr, Harald Räcke 9 Union Find

372

#### List Implementation

#### Lemma 28

An element is charged at most  $\lfloor \log_2 n \rfloor$  times, where n is the total number of elements in the set system.

#### Proof.

Whenever an element x is charged the number of elements in x's set doubles. This can happen at most  $\lfloor \log n \rfloor$  times.
# **Implementation via Trees**

- Maintain nodes of a set in a tree.
- The root of the tree is the label of the set.
- Only pointer to parent exists; we cannot list all elements of a given set.

# Implementation via Trees

To support union we store the size of a tree in its root.

### union(x, y)

- ▶ Perform  $a \leftarrow \operatorname{find}(x)$ ;  $b \leftarrow \operatorname{find}(y)$ . Then:  $\operatorname{link}(a, b)$ .
- link(a, b) attaches the smaller tree as the child of the larger.
- In addition it updates the size-field of the new root.

• Time: constant for link(a, b) plus two find-operations.

### 377

# **Implementation via Trees**

### makeset(x)

- Create a singleton tree. Return pointer to the root.
- ▶ Time: *O*(1).

### find(x)

- Start at element x in the tree. Go upwards until you reach the root.
- Time: O(level(x)), where level(x) is the distance of element x to the root in its tree. Not constant.

# Implementation via Trees

### Lemma 29

The running time (non-amortized!!!) for find(x) is  $O(\log n)$ .

### Proof.

- When we attach a tree with root c to become a child of a tree with root p, then size(p) ≥ 2 size(c), where size denotes the value of the size-field right after the operation.
- After that the value of size(c) stays fixed, while the value of size(p) may still increase.
- ► Hence, at any point in time a tree fulfills  $size(p) \ge 2 size(c)$ , for any pair of nodes (p, c), where p is a parent of c.

# **Path Compression**

### find(x):

- Go upward until you find the root.
- Re-attach all visited nodes as children of the root.
- Speeds up successive find-operations.

Note that the size-fields now only give an upper bound on the size of a sub-tree.

	9 Union Find
🛛 🛄 🖓 🖾 © Ernst Mayr, Harald Räcke	

# Path Compression

Asymptotically the cost for a find-operation does not increase due to the path compression heuristic.

However, for a worst-case analysis there is no improvement on the running time. It can still happen that a find-operation takes time  $O(\log n)$ .

# **Path Compression**

### find(x):

- Go upward until you find the root.
- Re-attach all visited nodes as children of the root.
- Speeds up successive find-operations.

One could change the algorithm to update the size-fields. This could be done without asymptotically affecting the running time.

However, the only size-field that is actually required is the field at the root, which is always correct.

We will only use the other sizefields for the proof of Theorem 32.

 Note that the size-fields now only give an upper bound on the size of a sub-tree.

	9 Union Find	
UUUU©Ernst Mayr, Harald Räcke		379

# Amortized Analysis

### **Definitions:**

size(v) = the number of nodes that were in the sub-tree rooted at v when v became the child of another node (or the number of nodes if v is the root).

Note that this is the same as the size of v's subtree in the case that there are no find-operations.

- $\operatorname{rank}(v) \coloneqq \lfloor \log(\operatorname{size}(v)) \rfloor$ .
- ▶  $\Rightarrow$  size(v) ≥ 2<sup>rank(v)</sup>.

### Lemma 30

© Ernst Mayr, Harald Räcke

EADS

The rank of a parent must be strictly larger than the rank of a child.

# **Amortized Analysis**

### Lemma 31

There are at most  $n/2^s$  nodes of rank s.

### Proof.

- Let's say a node v sees node x if v is in x's sub-tree at the time that x becomes a child.
- A node v sees at most one node of rank s during the running time of the algorithm.
- This holds because the rank-sequence of the roots of the different trees that contain v during the running time of the algorithm is a strictly increasing sequence.
- Hence, every node *sees* at most one rank *s* node, but every rank *s* node is seen by at least  $2^{s}$  different nodes.

EADS	9 Union Find
🛛 🕒 🖯 🕲 Ernst Mayr, Harald Räcke	

# **Amortized Analysis** In the following we assume $n \ge 2$ . rank-group: • A node with rank rank(v) is in rank group $log^*(rank(v))$ . • The rank-group q = 0 contains only nodes with rank 0 or rank 1. • A rank group $g \ge 1$ contains ranks $tow(g - 1) + 1, \dots, tow(g).$ The maximum non-empty rank group is $\log^*(|\log n|) \le \log^*(n) - 1$ (which holds for $n \ge 2$ ). • Hence, the total number of rank-groups is at most $\log^* n$ .

# **Amortized Analysis**

We define

and

$$\log^*(n) := \min\{i \mid \text{tow}(i) \ge n\}$$

### Theorem 32

Union find with path compression fulfills the following amortized running times:

- makeset(x) :  $\mathcal{O}(\log^*(n))$
- find(x) :  $\mathcal{O}(\log^*(n))$
- union(x, y) :  $\mathcal{O}(\log^*(n))$

	9 Union Find	
🛛 🛄 🖓 🖾 © Ernst Mayr, Harald Räcke		383

# **Amortized Analysis**

### **Accounting Scheme:**

- create an account for every find-operation
- $\blacktriangleright$  create an account for every node v

The cost for a find-operation is equal to the length of the path traversed. We charge the cost for going from v to parent [v] as follows:

- If parent[v] is the root we charge the cost to the find-account.
- If the group-number of rank(v) is the same as that of rank(parent[v]) (before starting path compression) we charge the cost to the node-account of v.

9 Union Find

Otherwise we charge the cost to the find-account.

384

382

EADS

# **Amortized Analysis**

### **Observations:**

- A find-account is charged at most  $\log^*(n)$  times (once for the root and at most  $\log^*(n) - 1$  times when increasing the rank-group).
- After a node v is charged its parent-edge is re-assigned. The rank of the parent strictly increases.
- After some charges to v the parent will be in a larger rank-group.  $\Rightarrow v$  will never be charged again.
- The total charge made to a node in rank-group *g* is at most  $\operatorname{tow}(g) - \operatorname{tow}(g - 1) - 1 \le \operatorname{tow}(g).$

EADS © Ernst Mayr, Harald Räcke	9 Union Find	386

Amortized Analysis  
For 
$$g \ge 1$$
 we have  

$$n(g) \le \sum_{s=\text{tow}(g-1)+1}^{\text{tow}(g)} \frac{n}{2^s} = \frac{n}{2^{\text{tow}(g-1)+1}} \sum_{s=0}^{\text{tow}(g)-\text{tow}(g-1)-1} \frac{1}{2^s}$$

$$\le \frac{n}{2^{\text{tow}(g-1)+1}} \sum_{s=0}^{\infty} \frac{1}{2^s} \le \frac{n}{2^{\text{tow}(g-1)+1}} \cdot 2$$

$$\le \frac{n}{2^{\text{tow}(g-1)+1}} = \frac{n}{\text{tow}(g)}$$
Hence,  

$$\sum_{g} n(g) \text{ tow}(g) \le n(0) \text{ tow}(0) + \sum_{g\ge 1} n(g) \text{ tow}(g) \le n \log^*(n)$$

# **Amortized Analysis**

### What is the total charge made to nodes?

• The total charge is at most

$$\sum_{g} n(g) \cdot \operatorname{tow}(g)$$

where n(g) is the number of nodes in group g.

	9 Union Find	
🛛 💾 🛛 🖉 © Ernst Mayr, Harald Räcke		387

Amortized Analysis	
Without loss of generality we can assume that all makeset-operations occur at the start. This means if we inflate the cost of makeset to $\log^* n$ and add this to the node account of $v$ then the balances of all node accounts will sum up to a positive value (this is sufficient to obtain an amortized bound).	
9 Union Find	389

9 Union Find

### **Amortized Analysis**

The analysis is not tight. In fact it has been shown that the amortized time for the union-find data structure with path compression is  $\mathcal{O}(\alpha(m, n))$ , where  $\alpha(m, n)$  is the inverse Ackermann function which grows a lot lot slower than  $\log^* n$ . (Here, we consider the average running time of m operations on at most n elements).

There is also a lower bound of  $\Omega(\alpha(m, n))$ .

# Implementation 2: Summary Array

The bit for a key x is contained in cluster number  $\left|\frac{x}{\sqrt{u}}\right|$ .

Within the cluster-array the bit is at position  $x \mod \sqrt{u}$ .

For simplicity we assume that  $u = 2^{2k}$  for some  $k \ge 1$ . Then we can compute the cluster-number for an entry x as high(x) (the upper half of the dual representation of x) and the position of x within its cluster as low(x) (the lower half of the dual representation).

 $x \circ y = 01110001_2.$ 

403

2: **if** *mincluster* = null **return** null:

3: *offs* ← cluster[*mincluster*].min();

7: return null;

• Running time is roughly  $3\sqrt{u} = O(\sqrt{u})$  in the worst case.

# Implementation 3: RecursionWe assume that $u = 2^{2^k}$ for some k.The data-structure S(2) is defined as an array of 2-bits (end of the recursion).

# **Implementation 3: Recursion**

Instead of using sub-arrays, we build a recursive data-structure.

S(u) is a dynamic set data-structure representing u bits:

# **Implementation 3: Recursion**

The code from Implementation 2 can be used unchanged. We only need to redo the analysis of the running time.

Note that in the code we do not need to specifically address the non-recursive case. This is achieved by the fact that an S(4) will contain S(2)'s as sub-datastructures, which are arrays. Hence, a call like cluster[1].min() from within the data-structure S(4) is not a recursive call as it will call the function array.min().

This means that the non-recursive case is been dealt with while initializing the data-structure.

•  $T_{\text{del}}(u) = 2T_{\text{del}}(\sqrt{u}) + T_{\min}(\sqrt{u}) + 1.$

2: summary.insert(high(x));

### **Implementation 3: Recursion**

 $T_{\rm ins}(u) = 2T_{\rm ins}(\sqrt{u}) + 1.$ 

Set  $\ell := \log u$  and  $X(\ell) := T_{ins}(2^{\ell})$ . Then

$$X(\ell) = T_{\text{ins}}(2^{\ell}) = T_{\text{ins}}(u) = 2T_{\text{ins}}(\sqrt{u}) + 1$$
$$= 2T_{\text{ins}}(2^{\frac{\ell}{2}}) + 1 = 2X(\frac{\ell}{2}) + 1$$

Using Master theorem gives  $X(\ell) = \mathcal{O}(\ell)$ , and hence  $T_{\text{ins}}(u) = \mathcal{O}(\log u).$ 

The same holds for  $T_{\max}(u)$  and  $T_{\min}(u)$ .

 $T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1$ :

Set  $\ell := \log u$  and  $X(\ell) := T_{\text{mem}}(2^{\ell})$ . Then

$$X(\ell) = T_{\text{mem}}(2^{\ell}) = T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1$$
$$= T_{\text{mem}}(2^{\frac{\ell}{2}}) + 1 = X(\frac{\ell}{2}) + 1 .$$

Using Master theorem gives  $X(\ell) = \mathcal{O}(\log \ell)$ , and hence  $T_{\text{mem}}(u) = \mathcal{O}(\log \log u).$ 

EADS © Ernst Mayr, Harald Räcke 10 van Emde Boas Trees 414

# **Implementation 3: Recursion** $T_{\text{del}}(u) = 2T_{\text{del}}(\sqrt{u}) + T_{\min}(\sqrt{u}) + 1 \leq 2T_{\text{del}}(\sqrt{u}) + \frac{c}{\log(u)}$ Set $\ell := \log u$ and $X(\ell) := T_{del}(2^{\ell})$ . Then $X(\ell) = T_{del}(2^{\ell}) = T_{del}(u) = 2T_{del}(\sqrt{u}) + c \log u$ $= 2T_{\text{del}}(2^{\frac{\ell}{2}}) + c\ell = 2X(\frac{\ell}{2}) + c\ell$ . Using Master theorem gives $X(\ell) = \Theta(\ell \log \ell)$ , and hence $T_{\text{del}}(u) = \mathcal{O}(\log u \log \log u).$ The same holds for $T_{\text{pred}}(u)$ and $T_{\text{succ}}(u)$ .

# **Implementation 4: van Emde Boas Trees**

### Advantages of having max/min pointers:

- Recursive calls for min and max are constant time.
- min = null means that the data-structure is empty.
- min = max ≠ null means that the data-structure contains exactly one element.
- We can insert into an empty datastructure in constant time by only setting  $\min = \max = x$ .
- We can delete from a data-structure that just contains one element in constant time by setting min = max = null.

EADS

5

10 van Emde Boas Trees

# **Implementation 4: van Emde Boas Trees**

Note that the recusive call in Line 7 takes constant time as the if-condition in Line 5 ensures that we are inserting in an empty sub-tree.

The only non-constant recursive calls are the call in Line 6 and in Line 9. These are mutually exclusive, i.e., only one of these calls will actually occur.

From this we get that  $T_{ins}(u) = T_{ins}(\sqrt{u}) + 1$ .

### Space requirements:

The space requirement fulfills the recurrence

 $S(u) = (\sqrt{u} + 1)S(\sqrt{u}) + \mathcal{O}(\sqrt{u}) .$ 

- Note that we cannot solve this recurrence by the Master theorem as the branching factor is not constant.
- One can show by induction that the space requirement is S(u) = O(u). Exercise.

# Note that only one of the re-

Note that only one of the possible recusive calls in Line 9 and Line 11 in the deletion-algorithm may take non-constant time.

To see this observe that the call in Line 11 only occurs if the cluster where x was deleted is now empty. But this means that the call in Line 9 deleted the last element in cluster[high(x)]. Such a call only takes constant time.

Hence, we get a recurrence of the form

**Implementation 4: van Emde Boas Trees** 

$$T_{\text{del}}(u) = T_{\text{del}}(\sqrt{u}) + c$$
.

This gives  $T_{del}(u) = O(\log \log u)$ .

	10 van Emde Boas Trees	
🛛 🕒 🛛 🖉 Ernst Mayr, Harald Räcke		426

Let the "real" recurrence relation be

$$S(k^2) = (k+1)S(k) + c_1 \cdot k; S(4) = c_2$$

• Replacing S(k) by  $R(k) := S(k)/c_2$  gives the recurrence

 $R(k^2) = (k+1)R(k) + ck; R(4) = 1$ 

where  $c = c_1/c_2 < 1$ .

- Now, we show  $R(k) \le k 2$  for squares  $k \ge 4$ .
  - Obviously, this holds for k = 4.
  - For  $k = \ell^2 > 4$  with  $\ell$  integral we have

$$R(k) = (1 + \ell)R(\ell) + c\ell$$
  
$$\leq (1 + \ell)(\ell - 2) + \ell \leq k - 2$$

• This shows that R(k) and, hence, S(k) grows linearly.
